Conceptualizing, researching, and teaching social studies—including history and the social sciences—is a daunting endeavor. The field varies significantly across national contexts, often faces significant social and political constraints on its content, and is subjected to ongoing and frequently rancorous debates about its nature and purpose. This chapter describes the social and academic contexts that shape social studies curriculum and instruction, including diverse and conflicting perspectives on its content, but it also outlines convergent findings on teaching and learning the subject. In particular, the chapter describes how research has shown that students’ in-school learning is influenced by their social backgrounds and experiences, and that these often have an affective component that cannot be ignored in school. To promote deeper learning and engagement, meanwhile, educators not only must attend to students’ prior ideas but also should engage them in classroom discussion, alongside active investigation of meaningful issues.

Social studies as a school subject

Social Studies refers to a group of school subjects aimed primarily at developing elementary and secondary students’ understanding of society and social relations. Use of the term *social studies*, however, varies across national settings. In some countries, *social studies* is an umbrella term that includes separate and specific school subjects such as history, human geography, economics, and government. Less commonly taught subjects such as psychology, sociology, and anthropology also are usually considered part of social studies. In other countries, *social studies* is a single subject that focuses primarily on contemporary social issues and is taught separately from history, geography, and other social sciences, although it usually incorporates content from those subjects as well. In some countries, *social studies* is the elementary-level equivalent of separate secondary subjects and features separate lessons or units on each of these, with varying levels of integration across subjects. And in still other countries, the term is not used in schools, and the constellation of subjects dealing with society are simply referred to with a designation such as *history and social sciences*. Although the term *social education* is a more comprehensive way of referring to these various configurations of subject matter, and is used by some scholars and professional organizations, that term has not been widely adopted.

Regardless of how these subjects are referred to or organized in particular settings, students’ learning can be understood only by considering the societal purposes that the subjects serve. Because social studies touches on fundamental social and political processes—including national identity, civic participation, international relations, and racial and religious conflict—the subject can be highly controversial, and in many countries the curriculum is a continuing object of cultural and ideological dispute (e.g., [Baildon et al., 2014](#); [Bentrovato et al., 2016](#); [Taylor and Guyver, 2012](#)). Moreover, social studies in schools is influenced by a variety of forces, including not only curriculum documents and instructional materials but also cultural expectations, community pressure, administrative guidelines, and teachers’ own knowledge and beliefs ([Fitchett et al., 2014](#); [Ho et al., 2014](#); [Marker and Mehlinger, 1992](#); [Thornton, 2005](#)). As a result, official curricula and classroom practices often are only loosely connected, and the perspectives and recommendations of scholars in the field typically differ from both of these. Understanding students’ learning in social studies, then, requires consideration of what students are expected to learn and the opportunities they have to do so.

Purposes of learning social studies

The most basic distinction of perspectives in the field is between those that accept and embrace social and civic purposes for social studies, and those that downplay these purposes in favor of individual development or purportedly academic and disciplinary goals. In addition, within the large group of teachers, scholars, and educational agencies that aim to orient the subject toward social and civic life, a further distinction is crucial: Between those whose primary goal is to socialize students into the existing social

structure, and those who see social studies as a means for developing critical capacities that can lead to societal transformation (Thornton, 1994). Although there are important areas of overlap among each of these perspectives, the conceptual distinctions among them profoundly influence the knowledge, skills, and dispositions promoted in schools. Analyzing these differences helps clarify why discussions of social studies are contentious, why existing curricula contain inconsistent and even conflicting content, and why research on learning has been difficult to systematize.

Socialization usually involves developing a sense of national identification and pride (Barton and Levstik, 2004; Thornton, 1994; VanSledright, 2008). This may be attempted through history lessons, patriotic exercises, and holiday celebrations that emphasize national origins and significant political developments in the national past, all of which are typically presented as objects of veneration rather than of critical analysis. In some settings, this approach involves stories of national triumph or suffering and may aim to develop explicit support for ruling regimes, or even to evoke national or ethnic supremacy (Carretero, 2011; Lall, 2008; Papadakis, 2008). In other settings, socialization takes more inclusive forms, by celebrating racial, ethnic, or religious diversity, or aims to develop national identification in more subtle ways, such as through repeated emphasis on national achievements and exclusion of other countries, radical viewpoints, and controversial events or policies (Barton and Levstik, 2004; Ho, 2017; Torney-Purta et al., 1999). These latter approaches are particularly common at the primary level, where apart from occasional celebrations of national heroes, the curriculum largely focuses on simplified and idealized depictions of how local communities are organized, including community services, forms of employment, and geographical features (Brophy and Alleman, 2009; Halvorsen, 2017). The overall goal of this perspective is to enable students to fit into existing society, or at least into an officially promoted view of that society.

A second group of approaches is equally concerned with students' relation to society but aims to develop a more critical, even oppositional, approach to existing social relations (e.g., Busey and Walker, 2017; Engebretson, 2018; Ross, 2017). This usually involves guiding students in identifying societal issues and problems, examining their causes, and making individual or group decisions about how to respond (and often, taking direct action to do so). Toward that end, students study (depending on setting) topics such as racism, sexism, homophobia, economic inequality, Indigenous rights, political oppression, warfare, global inequality, and other pressing societal concerns, whether situated in the past or present. (At the primary level, issues are sometimes more local and immediate, such as food insecurity or the needs of the elderly in the local community). To the extent that individuals or events are celebrated in this approach, examples are typically drawn from activists or protest leaders and their work, although these too are most often chosen from a national framework. Often, this approach is oriented toward achieving superordinate societal goals, such as democracy (Parker, 2003), harmony and justice (Barton and Ho, 2022), or intercultural understanding (Nordgren and Johansson, 2015).

Whereas socialization has the sanction of both tradition and official requirements, critical perspectives have a less pervasive and secure place in the curriculum. Although widely promoted by scholars, in practice they usually depend on efforts of individual educators at the classroom or school level, and implementation takes a wide variety of forms. Especially at the secondary level, critical approaches often are associated with deliberation of controversial issues or with direct social and political action (Wood et al., 2013; Ho et al., 2017; Levinson, 2012). Other times, including but not limited to the primary grades, schools may avoid political topics in favor of transforming relationships among individuals and groups, with the goal of developing more tolerant, supportive, and just interactions, with or without a corresponding focus on the systemic forces that reinforce social divisions (Cremin and Bevington, 2017; Parker and Bickmore, 2020; Zembylas, 2016). In some settings, critical perspectives are part of civics or history, but where those subjects are more constrained, they may be incorporated in other courses or promoted as part of programs such as *human rights education*, *peace education*, *sustainability education*, *multicultural education*, or *global education*.

The third perspective on social studies education eschews patriotic nationalism and other forms of political indoctrination but also holds critical perspectives at arm's length. The overarching goal of this perspective is to teach "academic" content, particularly that which is drawn from university-based disciplines such as history, geography, and economics (e.g., Lambert, 2016; Reisman, 2012; Shanahan and Shanahan, 2016). In some settings, this leads to an emphasis on procedural knowledge, such as how to engage in geographic inquiry or how to develop supportable conclusions from historical evidence. In other settings, the emphasis is not on the procedures of these disciplines but on the substantive conclusions of scholars. Economics education, for example, is strongly oriented toward developing students' understanding of economic concepts and principles (Council for Economic Education, 2010), while in some countries the chief concern of history educators is to align content with current scholarship, so that students are not learning outdated or mythic interpretations (e.g., Kang, 2016).

Civics or citizenship education has a more fraught relationship with this perspective, in part because there is no university discipline called "civics," and the closest analog, political science, differs substantially from the content of most school courses. Nonetheless, a major goal of many civics courses is for students to learn about the structure and function of government (including principles such as popular sovereignty, the rule of law, separation of powers, and so on, as well as methods for influencing politics), and in this form it mirrors the emphasis on learning a body of substantive and procedural knowledge. Across all social studies subjects, particularly at the secondary level, the most common manifestation of the academic perspective consists of this kind of attempt to cover the content of textbooks and official curricula, with little thought given to its implicit or explicit purposes. Many educators—and the wider public—simply equate such official documents with academic disciplines, even though much of the content derives solely from traditions of school subject matter with little connection to current scholarship.

There are important areas of overlap between critical and academic approaches, but also important differences. Both emphasize conceptual understanding rather than memorization or routine application of knowledge; with some exceptions, both focus on procedures of investigation and the use of evidence; and both typically include consideration of multiple perspectives and

interactions or negotiation among competing interests. Academic approaches differ from more critical ones, however, in devoting less attention to students' attitudes, such as commitments to equality, human rights, or political participation. Although such attitudes may be an implicit goal of disciplinary approaches, these are usually considered indirect or secondary outcomes. For example, learning to use evidence to reach conclusions in history or geography should enable students to engage in the same practices when they consider contemporary affairs, and learning about the history of racism, colonialism, or other crucial social issues should not only alert students to the importance of these topics but provide alternatives to popular (and often divisive) understandings. Similarly, learning about concepts such as due process or human rights is frequently assumed to lead to a commitment to such principles. There is, however, limited evidence to support the claim of indirect effects of such academic knowledge (Hicks et al., 2012), and the field is not characterized by any coherent theory of how such outcomes would materialize.

Constraints on research in social studies

The diverse, even conflicting and contradictory, set of purposes for social studies constrains research that seeks to identify a set of straightforward principles of learning in the subject. In the most obvious sense, without agreement on the goals to be achieved, it is difficult to develop a systematic set of research-based recommendations for promoting learning. With some educators prioritizing socialization, others critical perspectives, and others academic ones, comparable analysis of differing settings becomes nearly impossible. As a result, research programs in social studies frequently are difficult to compare and synthesize. Learning to be patriotic, to confront systemic racism, and to analyze data on settlement patterns are likely to make use of very different cognitive processes, and it is difficult to imagine a coherent and useful perspective on learning that would encompass all of them, except at the most general level. This multiplicity of approaches is further complicated by national differences in both scholarship and school curricula, because the very nature of socialization and political action differs across countries (Hahn, 2010). Depending on setting, for example, national ideals may focus on progress, freedom, harmony, grievance, or ethnic identity. Similarly, social action in different settings might be oriented toward community reconciliation, participation in mainstream politics, or popular resistance and civil disobedience. Even academic subjects differ across countries, and so researchers sometimes investigate purportedly disciplinary practices that seem marginal or irrelevant to those in other settings.

The diversity of curricular purposes has other and perhaps more significant consequences for research on learning. One of the most important is that educational practice rarely displays a systematic concern with any one goal. Instead, most official and enacted curricula contain a miscellaneous assortment of socializing exercises, academic content, and attention to societal issues, combined with directives from politicians, recommendations by professional lobbying groups, and the strong hand of tradition. As a result, researchers have difficulty identifying natural settings in which they can investigate any consistent set of curricular goals. Often, in order to secure study sites, researchers in social studies must design instructional interventions that are sufficiently brief and structured that teachers are willing to implement them without disrupting the rest of their curriculum. Such interventions, however, may be so simplified that they fail to address either substantive curricular goals or the daily practice of educational institutions. Some investigators have engaged in designed-based research (e.g., Parker et al., 2018; Rubin et al., 2019) in order to enhance the possibility of collecting more focused data, as well as to promote more ethical and collaborative research, but the number of educators who are willing to take part in such projects—which often represent a major departure from common practice—may be limited.

Contributing to this divide between scholarship and practice is the disparity between the most prevalent curricular goals and the interests of scholars. On the one hand, few researchers are interested in investigating the socializing function of social studies, particularly in its common patriotic or nationalistic forms. Although research on political socialization was once common, most educational scholars today reject the importance of studying how to develop students' allegiance to the nation-state through formal education. To the extent that they are interested in this topic, their research focuses on how schools aim to blunt critical perspectives (e.g., Heilig et al., 2012; Sabzalian et al., 2021); how students' social identities develop outside formal schooling (e.g., Lévesque and Croteau, 2022; Levy, 2014); and how students may ignore or resist the socializing function of schooling (e.g., Choi et al., 2011; El-Haj, 2007; Harris and Reynolds, 2014). On the other hand, many teachers are just as reluctant to engage in practices that involve critically examining societal issues, particularly since these inevitably are controversial and thus spark fears of community resistance, uncontrolled emotional reactions from students, or teachers' own pedagogical limitations (reviewed in Ho et al., 2017; Pace, 2019). Although academic approaches are often considered "safer," and thus easier to investigate in naturalistic settings, these too frequently can lead to controversial perspectives that teachers would rather avoid, or that they may find threatening to their own worldviews (James, 2008).

Learning in social studies

Despite obstacles to research on the effectiveness of instructional methods, a substantial body of knowledge exists that is relevant to understanding how students' ideas develop. A number of handbooks on social studies education and its constituent subjects (Arthur et al., 2008; Carretero et al., 2017; Davies et al., 2018; Levstik and Tyson, 2008; Manfra and Bolick, 2017; Metzger and Harris, 2018), along with synthetic reviews of research in the field (Aitken and Sinnema, 2008; Barton and Avery, 2016; Hicks et al., 2012), provide extensive and specific insight into findings related to learning, particularly with regard to history and civic education.

This research illustrates that students from a young age are active constructors of meaning; that their ideas have arisen in a variety of contexts; that ideas developed outside school interact in complicated ways with curriculum content; and that the social purposes of learning influence students' understandings. The following sections draw primarily from these prior reviews, supplemented by more recent research.

Learning in and out of school

One of the most basic findings of research on students' understanding of social studies is that they develop powerful ideas about the social world outside of formal schooling, due to their participation from an early age in civic activities, economic transactions, engagements with the past, and navigation of their physical and social environments. Each of these is mediated by social context—family, community members, institutions, and the media (Hauver, 2019; Kang, 2020; Woodson, 2019). From these sources, students not only acquire discrete facts but also develop more complex conceptual structures that influence their understanding of social interactions, spatial patterns, and change over time. Students in the early years of schooling, for example, already know that fashion, technology, and the built environment have changed over time, and they have at least rough ideas about the nature of those changes and their relative chronology.

Information and conceptual structures such as these can provide building blocks for formal instruction, provided that teachers systematically elicit and activate students' prior knowledge and make direct connections to new content. Educators must be aware, however, of the ways in which prior knowledge varies among individuals and groups. Because knowledge of the social world is closely tied to social context, students with differing experiences are likely to bring diverse understandings to the classroom. Students from dominant, majority, or privileged backgrounds typically have greater access to the knowledge prioritized at school, and this may leave students from other backgrounds at a disadvantage. All students, however, have relevant experiences that can provide the basis for learning, if educators are encouraged to elicit and incorporate their knowledge. Students whose parents are migrant agricultural laborers, for example, may have rich concepts of geography and economics that other students lack.

Although students' prior understanding can provide an important foundation for later learning, these ideas may also differ from formal curricula and, in some cases, present obstacles to instruction. In history, for example, younger students are more likely to have learned about how social and material culture have changed over time than about the kinds of legal and political history that often frames the subject in school. Similarly, outside school younger students typically encounter social relations in terms of interpersonal relationships, and they have limited opportunities to develop complex understandings of societal structures such as government or the economy (Barton, 2020). Older students may demonstrate some of these same patterns of thinking, but they may have existing insights into societal power relations when these are linked to their own experiences (Colley, 2019). Educators must be careful, then, not to assume that students uniformly have the foundational knowledge needed to make sense of curriculum content. Concepts related to societal institutions in particular are ideas that must be developed as part of formal instruction—through careful links to the prior knowledge that students do have—rather than starting points for learning.

Two areas in which students may have incomplete or misleading ideas are related to the use of evidence to reach conclusions, and consideration of perspectives that differ from their own. Findings related to both these areas come primarily from history education, but these patterns are likely to be representative of other aspects of social studies as well. Outside school, students typically have not developed an awareness of how historical knowledge is constructed from evidence such as documents, artifacts, and other original sources; instead, they often assume that knowledge of the past is handed down through word of mouth. Similarly, students may struggle to evaluate authors, sources, and evidence when engaging with online information about social and political topics (McGrew et al., 2018). Students can learn to evaluate sources through instruction, but breaking through their initial ideas is easier than developing deeper understanding. Students easily come to see that history depends on a variety of sources that are incomplete and inconsistent, for example, and that knowledge of the past is uncertain, but they have more trouble seeing how to use such sources to reach supportable conclusions. Rather than engaging in a careful synthesis of evidence, they sometimes dismiss all interpretations as "just an opinion," and consider one account as good as another.

Students often are aware that people in the past thought and acted differently than people today, but they sometimes attribute this to deficiencies of character or intelligence, rather than to the influence of differing historical contexts. Students who have greater historical knowledge, however, are better able to engage in such contextualization (Huijgen et al., 2017). Similarly, although younger students are aware of superficial cultural differences in the present, they may harbor simplified and stereotypical understandings that show little awareness of the reasons behind differing cultural patterns (Torres, 2019). As with learning about historical evidence, students can easily come to recognize that people in the past were not simply deficient versions of modern people, or that people from other cultures have differing beliefs and assumptions, but they have more difficulty imagining how the perspectives of people today may be superseded in the future, or how their own cultures may look to others. Present-day and local patterns of thought and action, that is, still serve as the norm to which other perspectives are compared.

Students' understanding of history also is heavily influenced by narrative structure, and this influence occurs at multiple levels. First, students often over-narrativize historical content, by simplifying it into a limited number of people, settings, and events, and by organizing that content into the problem-solution structure commonly found in fictional stories. In addition, students often assimilate new historical content not just into a general narrative structure but into specific narrative templates, such as "freedom and progress" or "struggle against hardship," even when these have limited applicability (Barton, 2021; Kim, 2018b). And finally,

students may rely on specific narratives with which they are already familiar as a basis for interpreting—and misunderstanding—other historical events and settings (Kim, 2018a; Santiago, 2017). These patterns, however, differ across countries and illustrate the pervasive impact of societal discourses on students' learning. Common historical narratives differ between and within countries, as do the templates that underlay specific narratives. Even the prevalence of narrative itself, particularly in school settings, varies across countries, and this influences students' understanding of the past.

The affective nature of learning social studies

The most pervasive historical narratives almost always are connected to contemporary social and political events, and this connection illustrates an inescapable aspect of learning social studies: the affective salience of much of the content (Garrett et al., 2020). Current political issues often inspire deeply emotional reactions, and history often touches on topics that involve violence, tragedy, and trauma experienced by communities with which students identify. As a result, students' reactions to both contemporary and historical issues often have a strong affective component, and this may either motivate civic action or cause students to turn away from difficult topics (Abowitz and Mamlok, 2019; Miles, 2019). Students' affective connection to issues and identities also influences how they evaluate historical and contemporary sources, as they often dismiss those that do not align with their prior commitments (Jacobsen et al., 2018; Stoddard and Chen, 2018).

In addition, because much of social studies aims, implicitly or explicitly, to develop a sense of national identity among students—and frequently to develop allegiance to particular governmental structures or even specific leaders—students' social identities, and the relationship of their communities to the nation or the state, intersect in important ways with formal learning. Historical narratives that students learn in their communities may be unrelated to, or in opposition to, those they encounter in schools, which typically ignore or downplay forms of systematic oppression, and often omit or misrepresent the experience of minorities, as well as women and other groups who have historically lacked power (Crocco, 2001; King and Brown, 2014; Rodríguez, 2018; Sabzalian, 2019; Thornton, 2002). Even the seemingly uncontroversial content of most elementary curricula in social studies, which usually emphasizes local neighborhoods and communities, often presents a simplified and idealized version of society that has little connection to many students' lives.

As a result of this potential disparity between identities promoted within and outside school, students who identify with oppressed or marginalized groups, or who belong to immigrant or undocumented groups, may ignore or resist much of the content of social studies, or simply find it irrelevant to their own lives. Other times, they may develop fluid, shifting, and complex identities with multiple allegiances (Bondy, 2016; Hahn, 2020), or draw on historical and contemporary content learned both in and out of school as they develop their own interpretive frameworks (Barton, 2012; Johnson, 2019; Yoder, 2020). Similarly, although students from all backgrounds have experience with civic practices, these may reflect forms of public participation that have limited connection to the mainstream ideas they are expected to learn at school (Clay and Rubin, 2020), and their own ideas about civic identity may be grounded in affective attachments and boundaries that transcend a given nation-state (Keegan, 2019). And because social studies often touches on conflicting perspectives, differing political opinions, and controversial issues, students' ideas may be influenced by their own, socially-situated ideological commitments, interpretative frames, and emotional reactions (Colley, 2019). Not only students' ideas but also their willingness to engage in civic activities and discussions is influenced by affective factors, including the relationships they have with others, their assessment of the trust they can feel toward others, their feelings of empathy, their sense of agency, and their judgments of risk (Bellino, 2017; Hauver, 2019).

Influence of instruction

Despite the numerous ways in which factors external to schooling contribute to and intersect with students' learning, formal instruction does have an important influence on students' understanding, including for the youngest students. This seems an unremarkable observation, but it stands in contrast to two long-standing assumptions of some scholars and educators: (1) That historical reasoning is too difficult for any but the most advanced students; (2) That civic and political attitudes are largely impervious to specific interventions at school. Decades of research, though, have now undermined these misconceptions and have provided insight into the impact of instruction. Most of this research has focused on the pedagogical tasks that lead to "deep processing" of content (Hicks et al., 2012) and that are associated with cognitive and affective gains.

Numerous studies from a variety of settings, and using differing methodologies, have demonstrated that classroom discussion (in which students engage in in-depth, substantive exchange of ideas) and an open classroom climate (in which students are encouraged to share their opinions freely) are associated with a variety of positive outcomes. These include greater knowledge, more empathy and tolerance, better argumentation, higher levels of perceived political efficacy, and greater intention of voting and engaging in other aspects of public participation. Some studies have separated the effect of discussion and climate from other aspects of instruction, but most interventions include these in combination with other tasks, so their discrete impact is not always obvious. Most social studies educators assume that discussion and an open climate are required for any effective instructional procedure, and conversely, that the exchange of ideas without substantive content would be pointless.

Another body of research investigates the impact of activities that engage students in analyzing and drawing conclusion from evidence, such as geographic data or historical documents and artifacts. These studies have shown that such investigation-oriented tasks, particularly when combined with products such as writing essays or developing presentations, usually are associated with greater knowledge construction by students; longer, more accurate, and more thesis-based products; better understanding of

causal relations, and increases in cultural awareness and empathy (Schlemper et al., 2018). Similarly, engaging in simulations of political processes such as the United Nations or national legislative assemblies—which also require investigation, synthesis, and presentation of information—usually are associated with greater student engagement, as well as gains in knowledge, political efficacy, and perspective-taking (Levy, 2018). Notably, however, many of these studies show mixed findings, with some outcomes better supported than others, or with results that intersect with other variables such as reading level. In addition, this body of research consistently points to the importance of carefully structured instructional supports, even when problems themselves are unstructured.

One of the most troubling findings from research on instructional practices in social studies is that discussion- and investigation-oriented pedagogies are more likely to be offered to students from higher income backgrounds, of higher academic achievement, and (in the United States) who are White. Students in lower academic tracks, and immigrant or transnational students (or those who are assumed to be), can also experience negative and limiting messages from schools about their roles in society, along with lower expectations for future political participation (Dabach, 2014; Salinas, 2006). These experiences are not uniform, however, and high expectations and high-quality instructional practices can encourage young people from marginalized backgrounds to engage productively with social studies content and to develop positive civic identities (Callahan and Obenchain, 2013).

Conclusions

In order for social studies to be a meaningful subject of study, educators must attend to the ideas students bring with them. These ideas have been developed through students' own life experiences, as they participate in local, national, and even global communities. Without attention to these ideas, instruction at school will be both ineffective (because it does not build on students' prior knowledge or attend to gaps in their understanding) and irrelevant (because it fails to address perspectives and practices that students consider important). Schools cannot, that is, attempt to deliver a social studies curriculum that fails to engage with the social experiences of students themselves. Only by connecting with students' backgrounds—in all their complexity and diversity—can social studies deepen and enrich their ideas, so that students better understand the social world.

Connecting with students also means developing clarity about the subject's purpose. Students live in a world with immense social problems—hunger, poverty, racism, homophobia, gender discrimination, warfare, and other persistent issues. Many students and their communities experience these problems themselves, and all must play a role in solving them. Social studies that aims to indoctrinate students or develop an uncritical acceptance of the status quo can never be relevant to the issues that have meaning for students, and can only be a tool of further oppression. Academic or disciplinary approaches are hardly any better, for they too distance the subject from topics that matter in the real world, with little more than an unfounded hope that students may someday find their content useful. Social studies and its constituent subjects must seek a new path forward, one that directly engages students in using evidence to deliberate contemporary social issues. Educators may find it threatening to confront difficult and controversial questions, but only by doing so can social studies contribute to a more just and harmonious future.

Introduction and overview

A comprehensive characterization of learning in mathematics calls for the careful examination of (a) the nature of learning, (b) what is intended to be learned, and (c) the nature of learning environments and the impact they have on learning. Researchers' understandings of these aspects of learning have evolved over the 20th and early 21st centuries, with significant growth in recent decades as mathematics education coalesced and matured as a discipline.

Characterizing learning in general, and specifically in mathematics provides and elaborates on characterizations of learning in general and mathematics learning in particular, the latter being:

Mathematics learning is change in a person's understanding of mathematical content, practices, habits of mind, orientations and mathematical identity that results from that person's classroom and other experiences.

Central ideas in **Characterizing learning in general, and specifically in mathematics** include a broad characterization of mathematical thinking (the goal of instruction) that encompasses knowing mathematical content and practices, developing powerful mathematical habits of mind, and developing productive mathematical orientations (including beliefs and dispositions) and a positive mathematical identity. Mathematics learning involves not only mathematical content and practices, but also misconceptions, changes in one's sense of the discipline, and changes in one's mathematical identity. It includes not only what students take from classroom experiences but, in addition, what they come to understand from the social surround, for example, that mathematical proficiency might be innate or learnable, or gender- or race-linked. All these understandings are consequential because they shape if and how one engages in mathematics.

Learning goals and learning outcomes addresses issues related to the mathematics curriculum and learning outcomes. Issues of standards and the formal curriculum—characterizations of what should be learned, when, and by whom—are in part social questions. They are typically addressed by governmental panels, with input from various stakeholder groups such as mathematicians, education researchers, teachers, and parents or political groups. Such goals (e.g., statistical or mathematical literacy) evolve as a function of societal needs and because of deepening understandings of learning processes (e.g., problem solving).

In addition to the formal curriculum, there are also the “hidden curriculum” and the unintended consequences of learning. The hidden curriculum involves the tacit but often strong messages students pick up about the nature of schooling—for example, how they should interact with peers, teachers, and other adults; how they should perceive different races, groups, or classes of people; or

what ideas and behaviors are considered acceptable or unacceptable (<https://www.edglossary.org/hidden-curriculum/>).” What is learned may include beliefs about what mathematics is, how mathematics is to be learned and done, and who is capable of doing mathematics.

Mathematical thinking and learning addresses the nature of knowing and learning, with a focus on mathematics. **Antecedents** describes philosophical and psychological antecedents to the current era, which began in the 1960s. As discussed in **Current understandings**, mathematics education began to coalesce as a discipline in the 1960s; the “cognitive revolution” began in the 1970s and mathematics education turned to a focus on cognitive processes. Studies of mathematical learning indicated that mathematical thinking, learning, and understanding involved not only acquiring knowledge but the development of problem solving skills, and that aspects of thinking such as metacognition and belief systems are central to the processes of learning and doing mathematics. Attention to such processes and their social origins evolved into a focus on socio-cognitive issues, grounded in the understanding that learning is a function of the practices in which one is engaged, and thus a function of interactions with others. This, of course, has implications both for learning goals (See **Learning goals and learning outcomes**) and learning environments (See **Productive learning environments**). Learning goals must include the development of metacognitive skills and robust mathematical beliefs as well as content knowledge and problem solving skills, and learning environments must be reconceptualized in ways that support the development of such understandings.

Productive learning environments addresses the nature of learning environments and their impact on mathematical thinking and learning. The key point, representing a change in the field’s understanding, is a change in focus from “teacher-centered” instruction to examining what instruction looks and feels like from each student’s perspective. Traditionally one would ask, “what kinds of teaching help students learn most effectively?” However, a main point of the section **Productive learning environments** is that learning is a sociocultural phenomenon—that what one learns (not only content, but processes and beliefs) is a function of interactions with others. Hence, while the teacher’s role remains central, equally critical issues concern the nature of the learning environment that the teacher creates, and how each student experiences it.

Once this shift in perspective is made, one can explore the attributes of learning environments that support productive engagement—not simply with regard to content learning, but with regard to the full range of learning described in **Mathematical thinking and learning**: the development of problem solving skills, powerful mathematical habits of mind, and productive mathematical orientations (beliefs and dispositions) including a sense of mathematical agency and positive mathematical identities.

Implications and prospects provides a brief discussion of the implications of the main ideas discussed in this entry and prospects for change.

Characterizing learning in general, and specifically in mathematics

This entry will use the following definition of learning:

Learning is a change in a person’s understanding or behavior that results from that person’s experiences.

Readers may be struck by the breadth of this characterization. This section explains why the definition is as encompassing as it is, and some of the consequences of having such a definition.

The phrase “that person’s experiences” encompasses the interpersonal aspects of interactions. This definition is inherently socio-cultural in character, for the reasons discussed below. There are other traditions, some of which are discussed in **Antecedents**. For an extensive review, see [Greeno et al. \(1996\)](#).

The term “understanding” refers to what an individual takes to be true, even if it is not true. This usage differs from everyday usage. The reason is that in any work that people do, what matters is what they take to be true. For example, the student who considers the incorrect equation $(a + b)^2 = a^2 + b^2$ to be correct will employ that understanding when solving algebraic problems.

Accordingly, the use of the term “change” (as opposed to “growth”) in the definition is consequential. In everyday usage learning is considered to be a gain in knowledge or a productive change in behavior, typically the result of deliberate instruction. This perspective reflects the traditional epistemological view of knowledge as fixed and immutable, and of learning processes as contributing to the growth of what an individual knows. Standard metaphors for this view include thinking of the learner as a blank slate to be written upon, or an empty jug to be filled with knowledge. In such a view, only the correct knowledge counts and the growth of knowledge is unidirectional.

However, as indicated by the algebra example given above, what an individual learns is not necessarily correct. Musicians or athletes may learn counterproductive techniques, and retraining to unlearn or overcome them can be a significant challenge. The same is the case with regard to learning a discipline. Extensive literatures on misconceptions in mathematics and science indicate that learners consistently develop misunderstandings that are, for at least some time, stable and predictable, for example, misunderstandings of the subtraction procedure that are so robust that researchers can predict the incorrect answers to problems that students will produce, before the students work the problems.

It is thus essential for any definition of learning to encompass the incorrect as well as correct understandings and behaviors that result from instruction. It is also essential to note that generalization is a natural human trait that underpins much learning. The

incorrect algebraic expression given above represents a natural, albeit incorrect, use of the distributive law, where the exponent 2 is “distributed” across the expression $(a + b)$. This kind of inappropriate generalization is a very common occurrence. Another is students’ thinking that “multiplication makes things bigger”—a truth when dealing with positive whole numbers that no longer holds when one is working with fractions.

These examples point to the fact that what is learned goes far beyond the intended content and process goals of instruction. Whether or not they are stated explicitly, students’ consistent mathematics-related experiences in classrooms (technically called sociomathematical norms) define for students what is considered legitimate mathematical behavior. Such understandings shape the ways in which students do mathematics. For example, students whose daily classroom experience consists of being shown how to solve certain kinds of tasks, after which they are given multiple practice exercises and subsequently tested on tasks that resemble the practice exercises, tend to develop the understanding that “all problems can be solved in just a few minutes.” The behavioral consequence of this learning is that many students stop working after just a few minutes when given richer and more substantial problems, when they might well solve them if they persevere. Similarly, students in a classroom where mathematical hypotheses or claims are expected to be accompanied by explanations of the type “I think/claim that this is true because ...” will come to incorporate the explanatory norms of doing mathematics as part of their understanding of the discipline. Even more broadly, there is the “hidden curriculum”: from their engagement in routine practices of schooling, students learn the (local, contextual) definitions of what it means to be a good student, how to behave appropriately, etc.

Some of what students learn in mathematics classes is deeply personal. Students are positioned not only by test results but by social interactions to see themselves as good or bad at mathematics, as fast or slow, to have particular strengths or weaknesses, and so on. These understandings about themselves have profound effects on the ways students engage in mathematics. Students’ mathematical identities—how they see themselves vis-à-vis mathematics—are fundamentally shaped by classroom experiences. This is consequential. Students are likely to engage in and with mathematics to the degree that they see themselves as mathematically proficient.

The mechanisms of learning are neither simple nor cumulative. People build complex networks of understandings, and unstable knowledge is often misremembered or forgotten. What a person currently understands shapes how new information is perceived. Information that fits into an individual’s knowledge network is more likely to be established and retained. Indeed, new and correct information may not take hold if enough connections to it are not built, and older, incorrect knowledge may regenerate. The more ways in which new information is connected to established knowledge, the more robustly it is retained. For example, research indicates that many students, when first studying the graphs of linear functions, develop the understanding that three pieces of information (the slope of the line, its x-intercept, and its y-intercept) are necessary to produce the graph of a line. This understanding persists for weeks and sometimes months. However, it tends to fade with experience. Ultimately almost all students come to understand the normative slope-intercept formula, in which only two pieces of information are necessary (Schoenfeld et al., 1993).

For all the preceding reasons, the definition of learning given above is necessarily broad. What must also be broad is the conception of mathematics to be learned. The question is, what does it mean to think mathematically? This encompasses far more than simply knowing established facts, procedures, and techniques. The goal of mathematics instruction is for students to become productive mathematical thinkers. That means having a solid knowledge base. In addition, it means having productive mathematical habits of mind—habits of inquiry and problem solving that enable the individual to make and verify mathematical connections. Being an effective mathematical thinker entails being metacognitive while solving problems—monitoring the process and making effective, reflective use of what one knows. It means having a positive mathematical identity, orientations, and a sense of agency—a willingness to engage with mathematical challenges in productive ways (See [Mathematical thinking and learning](#) for detail.). Given the fact that memory fades, a goal for mathematics learning cannot be that students will remember all the mathematics they have learned. Rather, it must be that students should remember and understand enough to regenerate the essential mathematics that they need to know and use.

Finally, it should be noted that mathematics learning is the result of activities inside and outside the classroom. Just as most students “know their ABCs” before entering the classroom, students develop some sense of number and geometry before they enter school. Similarly, some aspects of identity (e.g., “is mathematics for me?”) are shaped in significant ways by both in-school and out-of-school experiences.

Thus, an elaboration of the definition that began this section, with a focus on for mathematics learning is as follows:

Mathematics learning is change in a person’s understanding of mathematical content, practices, habits of mind, orientations and mathematical identity that result from that person’s classroom and other experiences.

The primary focus of this entry is on classroom learning, with an emphasis on the nature of learning environments from which students emerge as knowledgeable and resourceful mathematical thinkers and problem solvers.

Learning goals and learning outcomes

Nations across the globe employ varied mechanisms to specify the mathematics that students are expected to learn. Some educational systems are “top down.” For example, in the mid-to-late 20th century it was said, only partly in jest, that all 10th grade mathematics students in France could be found working the same problem at the same time. In Japan, curriculum specifications were developed at the national level, with a small number of textbook publishers developing and marketing curricula that complied with those specifications. In Germany, curricular goals were established by the sixteen German states. In the US, prior to the year 2000, a small number of the 50 independent states had legally mandated curricula, sets of accredited textbooks, and assessments. Across the US more than 15,000 local and regional school districts had the ostensible freedom to develop and implement curricula at will.

The phrase “ostensible freedom” is important because external constraints limited the degrees of freedom that school districts appeared to have. Expectations that students would enroll in calculus at the university level meant that there was a consistent “algebra to geometry to advanced algebra to trigonometry to pre-calculus” sequence across the US; consolidation in the textbook industry meant that school districts had a limited number of text options to choose from. (Elementary school math texts are typically sold in sets spanning the elementary grades, so that students in a district are committed to a particular instructional sequence. However, students who moved to other districts often found that their background did not mesh with their new district’s content sequence.)

Within the US, a strong trend toward homogenization began when the National Council of Teachers of Mathematics issued a volume of curriculum and evaluation standards in 1989. It continued through the issuance of Common Core State Standards (<http://www.corestandards.org/>) and aligned assessments in the 2010s. The standards and assessments were voluntary in that states could decide whether or not to adopt them; but with federal funding incentives for adoption, the year-by-year content sequences specified in the CCSS resulted in relatively consistent content specifications across the US.

Every nation has seen an evolution of curricular focus over time. Across the globe, curricula condensed over the course of the 20th century. In the US, Geometry, once a first-year college course, became a 10th grade course; calculus, once studied by advanced undergraduates, became a secondary school curricular option. Although there is some consistency in names and grade levels of mathematics courses across nations, there are curricular differences. In the Netherlands, for example, the curriculum is much more “applied” than in the US, a difference in emphasis reflected by the nature of the questions in two international mathematics examinations, PISA (Programme for International Student Assessment) and TIMSS (Trends in International Mathematics and Science Study). Nonetheless, the two examinations have a great deal in common, not only with one another but with almost all national exams and curricular standards documents. Universally, the general focus of mathematics curriculum and assessment is to determine what mathematics content a student has learned, with scant attention given to the practices and processes of doing mathematics.

As discussed in **Mathematical thinking and learning**, this focus on content means that a large part of mathematics proficiency—problem solving, metacognition, and students’ beliefs about self and the discipline—goes largely unaddressed in instruction. It is similarly unaddressed in testing, which is typically considered a measure of mathematics learning. Indeed, what has been called “mathematical literacy” (Burkhardt and Schoenfeld, this encyclopedia), the ability to use one’s mathematical knowledge to make consequential decisions in one’s daily life, gets very little meaningful attention. Before turning directly to those issues, however, we point to aspects of learning that are fundamentally unaddressed in curriculum documents. These pertain to the hidden curriculum and the role of mathematics in situating students, individually and collectively, in social and racial hierarchies.

The phrase “hidden curriculum” refers to the unwritten and often unacknowledged lessons conveyed to students by virtue of their participation in schooling. These lessons are often behavioral, concerning appropriate ways to comport oneself in school. Other lessons are learned as well. Practices such as “streaming” (alternatively, “setting” or “tracking”), which place students in different academic trajectories based in their perceived ability, send very strong messages about students’ perceived talents and futures. In the US, tracking correlates strongly with race—to the point where one research study (Shah, 2013) reports that an African-American student was asked “Oh you’re in this class? For real?” as he entered a high school precalculus class that was otherwise populated by whites and Asian-Americans. At the other end of the academic spectrum, remedial or low track mathematics classes tend to be populated predominantly by students of color. Being socially and academically positioned as not mathematically proficient shapes students’ identities and, in the case of tracking or streaming, can limit their potential learning opportunities in mathematics (see, e.g., Oakes, 2005).

Mathematical thinking and learning

Although mathematical thought has been the object of reflection by philosophers, mathematicians, and scientists for millennia and empirical studies of children engaged in mathematical tasks date to the early 20th century, mathematics education itself did not coalesce as a discipline until the 1960s. *Educational Studies in Mathematics* appeared in 1968, for example; *ZDM Mathematics Education* was first published (as *Zentralblatt für Didaktik der Mathematik*) in 1969; and the first issue of the *Journal for Research in Mathematics Education* appeared in 1970. Prior to that time, mathematics was the object of philosophical reflection and psychological experimentation, but learning to think mathematically was not an explicit focus of study.

Antecedents

Theories of mathematical thinking, teaching, and (tacitly) learning date to the ancient Greeks. The most notable example is the Meno dialog (Plato, 2005), in which Socrates uses a series of leading questions to demonstrate that a slave “knows” a special case of the Pythagorean theorem and that bringing that knowledge to mind is simply a matter of asking the right questions. This approach is now enshrined as the Socratic Method.

There is a long history of philosophical inquiry into the nature of thinking, but not of learning. Through history, mathematicians and scientists have reflected on their thinking (more than learning, as with philosophy), with little empirical substantiation. Thus, for example, Descartes wrote three volumes of *Rules for the direction of the mind*, on methods for solving problems; but these volumes were the product of introspection. The same is the case for Poincaré’s fabled description of his inspired discovery of the structure of Fuchsian functions. Poincaré described having worked deeply on the problem (the “saturation” phase of the Gestalt psychologists’ model of problem solving), taking a break from it (the incubation phase), having the answer come to him in a flash (the inspiration phase), and confirming the solution (verification). The challenge, however, was that such reports were anecdotal and not replicable. Other than providing vague guidance of the type, “work on the problem until you are completely immersed in it, then take a break, hoping for inspiration,” they hardly served as a basis for a theory of learning or instruction.

The Gestaltists were deeply concerned with mathematical structure, meaning, and understanding. Wertheimer’s (1945) critique of contemporary pedagogy emphasized that mathematics should make sense to students. He decried pure rote learning, noting, for example, that many students, trained by their experience, would laboriously calculate

$$\frac{274 + 274 + 274 + 274 + 274}{5}$$

without seeing that they were being asked to add a number five times and then divide by five, so the result had to be the number they started with. Wertheimer’s most famous example recounts his experience in a classroom where students were shown how to find the area of a parallelogram in “standard position,” as in Fig. 1A, but were nonplussed and considered it unfair when he asked them about the area of the identically shaped parallelogram in Fig. 1B; they had not been shown how to compute the areas of such figures.

Wertheimer’s (1945/1959) volume *Productive thinking* has many such examples, and suggestions for experiences students might have to help them develop deep understandings. As mathematically and pedagogically rich as it is, it has no theory of learning—in fact, the word “learning” is not in the index of the volume.

In sharp contrast, the behaviorists had both theories of learning and empirical data to back them up. The key idea was a theory of bonds, which characterized the strength of the relationship between stimuli and responses to them. Just as Pavlov’s dog learned to salivate at the sound of a bell when the bell ringing had been accompanied by Pavlov giving the dog treats, Thorndike’s law of effect posited that humans would learn to engage more frequently in behaviors that were associated with pleasure. Positive reinforcement would thus encourage particular behaviors, and negative reinforcement discourage others; in this way both non-human animals and people could be trained to perform complex acts. Thorndike, Skinner, and others applied the work done in animal training to human training, with educational theorists such as Gagné elaborating on how to break tasks into component parts that could be mastered through reinforcement.

Behaviorist theory captured aspects of skill acquisition well. When skills were carefully decomposed into learnable pieces and students were given appropriate practice and reinforcement, students learned them. However, the behaviorist approach is fundamentally limited. Behaviorists explicitly renounced “mentalism,” the idea that people have minds. The only things that counted as data in behaviorist theory were people’s objectively observable behaviors, the underlying theoretical idea being that all human actions can be explained without recourse to concepts such as “mind” or “thinking.” In consequence, important processes such as problem solving and creativity are not meaningfully encompassed within the theory. Behaviorism only addresses a small part of mathematical thinking and understanding, as elaborated in [Current understandings](#).

Fig. 1A A parallelogram in standard position.

Fig. 1B An identically shaped parallelogram in non-standard position.

The contemporary counterpoint to behaviorism was constructivism. Piaget's theory of genetic epistemology—where “genetic” is the adjectival form of “genesis,” meaning developmental, so the theory is a developmental theory of knowledge and understanding—centered on the development of people's understanding, starting with their neonatal understandings and proceeding through the point where, in adulthood, people became formal thinkers. Foundational in Piaget's work was his focus on understanding the world as seen by the child. For example, in *The child's conception of number*, Piaget and Szeminska (1941/1952) showed that many children younger than 7 years old would, when asked “does this (top) row (of coins or checkers) have more circles, does this (bottom) row have more circles, or do they have the same number of circles?” would answer “the same” if the objects were placed in two identical arrays as in Fig. 2A; but if they watched Piaget spread the objects in the top row, resulting in Fig. 2B, they would say that the top row had “more.”

Being able to understand that the two rows of objects in Fig. 2B contain the same number of objects is known as “conservation of number.” Piaget's observational/experimental research documented that coming to understand conservation of number is a developmental phenomenon: young children do not have this understanding, but (somewhat homogeneously) they do develop it at some point. Conservation of number was one of hundreds of developing understandings elaborated by Piaget.

Most important in Piaget's theorizing are the notions of constructivism and of genetic epistemology. Constructivism posits that people do not perceive the world directly, but that they build interpretive filters through which they interpret the information conveyed by their senses. (At the most basic level, this is obvious; if it were not the case, optical illusions would be impossible.) Piaget's work on genetic epistemology indicated that there was a great deal of consistency in the ways that humans develop those understandings (knowledge schemas) over time. Moreover, his theorizing included mechanisms of change—the notions of equilibration (roughly, settling into a stable set of knowledge schemas) and disequilibration (a disturbance of equilibrium), which will either result in assimilation (the incorporation of new information into established knowledge schemas) or accommodation (restructuring current schemas so that they better fit the new information). These mechanisms offer one way of characterizing the underlying mechanisms of learning.

Piaget was explicit about the fact that his was a theory of development, not a theory of learning. He was cautious about prescribing instruction except at a general level (e.g., that the learning experiences people are given should fit with their level of development). Much of Piaget's theorizing has been problematized, for example, the homogeneity of development (he did not adequately take into account variation in experience) and a failure to address the socio-cultural dimensions of learning. For that one turns to Vygotsky.

Vygotsky (1978) specifically addressed learning, arguing in essence that learning (whether in formal or informal settings, often the latter) resulted from the internalization of originally external operations. His best known example is a description of how an infant's reaching unsuccessfully for an object ultimately evolved into the infant's pointing to the object, after that child's reaching attempts were interpreted by the parent as calls for that object. This notion of “interiorizing” external interactions into internal thoughts is central to a socio-cultural perspective on learning. A major contribution of Vygotsky's theory is the concept of the Zone of Proximal Development, or ZPD—the space of understandings that is beyond an individual's competence when acting alone, but within reach when acting with guidance from or in partnership with a more knowledgeable other. The implication for instruction is that learning is optimal when students are working within their ZPD.

Two final antecedents paved the way for the phenomenal growth of mathematics education since the 1960s. The first is George Pólya. Writing in the spirit of Descartes, Pólya—one of the preeminent mathematicians of the 20th century—reflected on his own problem solving and wrote a series of volumes elaborating on problem solving heuristics, strategies typically used by mathematicians for making progress on challenging problems. The titles of Pólya's major books on problem solving—*How to solve it*, *Mathematical discovery*, and *Patterns of plausible reasoning*—all point to the dynamic, process-oriented ways in which mathematics is done. Pólya's books provide detailed elaborations of strategies, and the problems in them are sequenced so that working through the problems engages readers deeply with mathematics. Pólya's oeuvre contributed immeasurably to the teaching and learning of mathematical thinking, but, being practically rather than theoretically oriented, did not approach learning as a scientific endeavor.

Fig. 2A Equally spaced objects.

Fig. 2B Unequally spaced objects.

The field that did focus on learning as both a theoretical and empirical enterprise was cognitive science (now the “learning sciences”), which emerged as a multidisciplinary amalgam of many fields concerned with learning—anthropology, artificial intelligence, computer science, education, linguistics, philosophy, psychology, and sociology among others. The mix of disciplines challenged established paradigms and methods, bringing multiple perspectives and techniques to the study of learning. The notion of human as “information processor” was introduced; scientific models of thinking and learning were developed; and “rich, thick” observations of classrooms and the ways they shaped learning complemented previous statistical methods of measuring learning. Concurrently, mathematics education coalesced to the point where it would study the specifics of mathematics teaching and learning. This was necessary for significant progress, in that it is essential to wed a deep understanding of the nature of the discipline to be learned with the rigorous study of thinking, learning, and learning environments.

Current understandings

This section characterizes the spectrum of mathematical understandings that constitute mathematical proficiency and, more broadly, learning outcomes from schooling. They are, in order: mathematical content; mathematical processes and practices; meta-cognitive behavior; and belief systems and orientations.

Mathematical content

General issues of content specification were discussed in [Learning goals and learning outcomes](#). Brief descriptions of many nations’ educational systems, as well as characterizations of mathematics standards, frameworks, and curricula can be found at <http://timssandpirls.bc.edu/timss2015/encyclopedia/countries/>.

Mathematical processes and practices

The essence of mathematical proficiency consists of using what one has learned in the service of thinking mathematically (alternatively, mathematical sense making). Thinking mathematically involves fundamental processes such as abstracting, generalizing, proving, reasoning, representing, modeling and mathematizing, and solving problems. These processes and practices (mathematical habits of mind) should be central objectives for mathematics learning ([McDougal, 2017](#); [Schoenfeld, 1985](#)).

This is a major arena in which mathematics curricula fall short. Once again, there is significant variation from nation to nation: one can say, for example, that Japanese curricula attend to issues of problem solving more than curricula in many other nations, and that curricula in the Netherlands emphasize mathematical modeling more than in many other nations (see, e.g., <http://timssandpirls.bc.edu/timss2015/encyclopedia/countries/japan/>). What follows is broadly the case, within such bounds of variation.

The two processes that have received the most curricular attention are problem solving and modeling.

There has, historically, been some confusion about problem solving. The broadly accepted definition of “problem,” for some decades, is that a problem is a task that a person wants to solve, and for which they do not have a solution method at hand. If a student has been shown how to solve tasks that are closely related in type to the task currently assigned, then that task is an exercise, not a problem. The goal of problem solving instruction is to prepare students to grapple successfully with tasks that they have not been shown how to solve. Research on problem solving was motivated by [Pólya \(1945/57\)](#). Building on these ideas, [Schoenfeld \(1985\)](#) and others elaborated on problem solving strategies to the point where it would be possible at all grade levels for students to learn problem solving strategies and, as is done in Japan, to develop their understandings of mathematics content by solving problems that engage the students with the nuances and complexities of the content.

This is not the current reality. In the US, the *Common Core State Standards for Mathematics* devote 87 pages to delineating content, but 3 pages to listing practices—of which one is problem solving. In Great Britain, a governmental research review document produced as this entry was being written (May 25, 2021 Research and analysis document, *Research Review Series: Mathematics—Gov.UK, 2021*) that was intended to serve as the underpinning for curriculum and assessment development used the term “problem” only in the sense of exercise, thus denying problem solving a place in the curriculum. More generally, testing and assessment focus on the content that is specified in the curriculum; under time pressure, teachers tend to focus on what is to be tested. As a result, students do not generally have opportunities to learn to become mathematical problem solvers. Students are unlikely to learn what they are not exposed to, and what is not valued (as indicated by its absence on tests.)

The absence in most nations of curricular support for mathematical modeling and mathematical literacy, the application of mathematical thinking to “real world” issues, is comparably problematic ([Burkhardt and Schoenfeld, 2022](#)). A purported virtue of mathematics is that students not only learn to think logically, but to use their mathematical understandings to make thoughtful decisions about issues they encounter in their lives outside of school. As in the case of problem solving, these skills are well understood: there is a well-documented “modeling cycle,” and empirical evidence that students can learn, when provided appropriate instruction, to mathematize—to represent “real world” phenomena and make mathematically sound judgments about them. As in the case of problem solving, students are not likely to learn what they are not taught.

The other productive mathematical habits of mind listed above have received less attention, especially at the K-12 level. Evidence indicates that grade-level-appropriate forms of reasoning and proving can be taught and learned from the early grades. However, such experiences are rare, with the result that learning to prove—whether in secondary school geometry classes or in undergraduate

courses requiring a facility with proof—is encountered by students as a major roadblock. Encountering such ideas late in the curriculum is like learning a second language without prior experience, as opposed to having picked up bits and pieces of it through the years. Opportunities for students to abstract and generalize are extremely rare.

Metacognitive behavior

Fig. 3 shows a timeline graph of two students working a mathematics task that was a problem in the sense described above: the task was unfamiliar, but it was known that they possessed the mathematical knowledge to solve it. The students read the problem, decided to try a particular solution approach, and pursued that approach until they ran out of time.

Over years and multiple studies, more than 50% of the timeline graphs of students working unfamiliar problems resembled Fig. 3. The key point is that, having chosen an inappropriate direction for their work, the students were guaranteed to fail to solve the problem unless they changed direction. The failure to take stock—to assess how successful they were being, and to consider alternatives—was a failure of what is called monitoring and self regulation, an aspect of metacognition.

Fig. 4 shows a timeline graph of two students working an unfamiliar problem, subsequent to their having taken a problem solving course that placed a significant emphasis on monitoring and self-regulation.

Each of the triangles in Fig. 4 represents a time when the problem solvers paused to assess how well their solution was going. Roughly 3 min into the solution, they questioned the efficacy of the approach they had taken, and they soon abandoned that approach. Roughly 6 and 7 min into the solution, they again took stock and decided to persevere; but about 11 min into their work they abandoned their second approach. There are never guarantees that one will find a solution, as they did, about 13 min into their attempt. However, what is guaranteed is that they would have failed to solve the problem had they not assessed and abandoned their first two attempts.

There is, then, clear evidence that monitoring and assessing—fundamentally important aspects of mathematical (and other) problem solving—can be learned. However, these skills go almost completely unaddressed in mathematics classrooms.

Orientations and identity

An individual's orientations (beliefs, dispositions, preferences, and values) are shaped both by personal experience and in what that person learns from or is told by others. In some countries, for example the US, people tend to hold the belief that mathematical talent is innate, that is, a person's level of mathematical skill and potential is fixed. In other countries, for example Japan, people tend to hold the belief that how well one does in mathematics depends on how hard one works at it—the harder one works, the more successful one will be. Such beliefs are consequential: those who believe they are untalented are much less likely to strive to do well than those who believe that hard work pays off. This is an example of how cultural understandings are internalized and shape personal behavior. In the US, cultural lore includes the widely held stereotypes that some Asians and Whites are good at mathematics, while people of Black and Latin heritage are not.

People's understandings regarding the nature of mathematics and their relationship to it (their mathematical identities) come in large measure from their personal experiences. In the case of mathematics, the primary source of such experiences is in the classroom. Patterns of classroom interactions over mathematics, with teachers and other students, become abstracted as individuals' belief systems. They shape the individuals' dispositions regarding mathematics, including their willingness to grapple with new challenges (their sense of mathematical agency), what they think matters in doing mathematics (e.g., how important is it to be able to explain why something is true?), and thus how they engage in mathematics.

In the US, for many years the predominant instructional mode was “demonstrate and practice”: the teacher showed students how to solve a particular kind of task and gave them closely related tasks to practice, both in class and as homework. Typically, such exercises were expected to be completed in just a few minutes. Exams often contained a large number of tasks that students were expected to know how to solve. (In one research study a 50 min test contained 20 tasks; shortly before the exam the teacher told the students that they needed to have practiced their work carefully, “because you won't have time to think.”) The Graduate

Fig. 3 A timeline graph of a typical student attempt to solve a non-standard problem. Reproduced with permission from Schoenfeld (1985).

Fig. 4 A timeline graph of two students working a problem after having finished a course in problem solving. Reproduced with permission from Schoenfeld (1985).

Record Exam in mathematics, taken by university students who hoped to enroll in graduate school, contained 65 “problems” to be worked on for at most 3 h. Years of such experience led students to develop expectations and understandings such as the following: mathematics is learned by internalizing the rules and procedures given to you by experts; problems will either be solvable in a few minutes or, if you have forgotten the method, not at all; speed matters; your innate talent is revealed by how well you do on tests and how you are seen (and positioned) by others. In contrast, there are classrooms where the sociomathematical norms differ from these—students are given opportunities to engage in problem solving, and to work collaboratively in generating and testing ideas and conjectures, and to provide explanations of their reasoning. Here students tend to develop much more productive beliefs about how one goes about doing mathematics.

People’s mathematical identities are shaped by cultural assumptions. These include: assumptions about who is likely to be good at mathematics, whether or not mathematical ability is fixed, and what math is and how useful it is for one’s future. Similarly, identities are shaped by the ways that schools position students via sorting mechanisms such as tracking or streaming; by classroom discourse, in which students are positioned by the teacher and other students, either explicitly or tacitly (under what circumstances does the teacher call on them, or fellow students ask for or listen to their contributions?); and by performance measures such as tests. As noted at the beginning of this subsection, people’s mathematical identities are consequential. People who see themselves as effective mathematical thinkers and problem solvers are more likely to engage with mathematics tasks and persevere at them than those who do not.

Productive learning environments

The preceding sections discussed key aspects of mathematical thinking and learning, and some of the ways in which schooling and the larger social environment shape learning outcomes. In considering learning and learning environments, it is essential to consider the complete spectrum of outcomes, ranging from mathematical content, practices, and habits of mind to belief systems, orientations, and the shaping of individuals’ mathematical identities. This section discusses a comprehensive framework for characterizing learning environments regarding their potential to support mathematics learning, the Teaching for Robust Understanding (TRU) framework (Schoenfeld and the Teaching for Robust Understanding Project, 2016; <http://truframework.org>).

A distillation of the framework is given in Fig. 5, which outlines five key dimensions of all learning environments, including mathematics classrooms. Research indicates that student outcomes correspond to the quality of the classroom environment, when characterized according to the framework. That is, the richer the learning environment is along the five dimensions, the more likely it is that students will emerge from instruction as knowledgeable and resourceful mathematical thinkers and problem solvers. As discussed below, this entails the shaping of metacognitive behavior, belief systems, orientations, and mathematical identities as well. The five dimensions of the framework are discussed in **Dimension 1, classroom affordances for mathematics learning** through **Dimension 5, formative assessment. Implications and Prospects** offers a brief summing-up.

Dimension 1, classroom affordances for mathematics learning

Dimension 1 focuses on the opportunities students have to develop the deep sense of mathematics described in **Mathematical thinking and learning**. This includes engagement with rich mathematical content—content organized in ways that, in the words of the Common Core, is focused and coherent. Students should be presented with opportunities to make connections, learn and use

The Five Dimensions of Powerful Mathematics Classrooms				
The Mathematics	Cognitive Demand	Equitable Access to Mathematics	Agency, Ownership, and Identity	Formative Assessment
<i>The extent to which classroom activity structures provide opportunities for students to become knowledgeable, flexible, and resourceful mathematical thinkers. Discussions are focused and coherent, providing opportunities to learn mathematical ideas, techniques, and perspectives, make connections, and develop productive mathematical habits of mind.</i>	<i>The extent to which students have opportunities to grapple with and make sense of important mathematical ideas and their use. Students learn best when they are challenged in ways that provide room and support for growth, with task difficulty ranging from moderate to demanding. The level of challenge should be conducive to what has been called “productive struggle.”</i>	<i>The extent to which classroom activity structures invite and support the active engagement of all of the students in the classroom with the core mathematical content being addressed by the class. Classrooms in which a small number of students get most of the “air time” are not equitable, no matter how rich the content: all students need to be involved in meaningful ways.</i>	<i>The extent to which students are provided opportunities to “walk the walk and talk the talk” – to contribute to conversations about mathematical ideas, to build on others’ ideas and have others build on theirs – in ways that contribute to their development of agency (the willingness to engage), their ownership over the content, and the development of positive identities as thinkers and learners.</i>	<i>The extent to which classroom activities elicit student thinking and subsequent interactions respond to those ideas, building on productive beginnings and addressing emerging misunderstandings. Powerful instruction “meets students where they are” and gives them opportunities to deepen their understandings.</i>

multiple representations, etc. They should have opportunities to engage in mathematics in ways that support the development of powerful mathematical habits of mind, e.g., engaging with problems and learning problem solving techniques, in ways that support the development of metacognitive awareness and performance; explicitly focusing on modeling and issues of mathematical literacy; and being supported in age-appropriate engagement with abstraction, generalization, and producing coherent chains of reasoning, argumentation, and proof.

In the absence of such opportunities for engagement, students are unlikely to develop the relevant understandings. However, opportunities for engagement are hardly enough to result in powerful learning. The nature of the engagement (See **Dimension 2, cognitive demand and the accessibility of ideas** through **Dimension 5, formative assessment** of the framework) is critically important.

Dimension 2, cognitive demand and the accessibility of ideas

When students are given work that they find too easy, there is little “cognitive demand” and little room for them to grow. On the other hand, mathematically rich presentations or task sets will do learners little good if the students do not find the ideas in them to be within reach. The instructional challenge is to arrange instruction so that the level of challenge supports productive struggle. More formally, the idea is for students to be working within their zones of proximal development, being able to build on what they know.

This is a significant instructional challenge. Mechanisms for easing the challenge include the use of problems that have multiple entry points and a range of possible solution methods. Individual students have a greater likelihood of gaining a foothold on such problems, meaning their engagement is more likely to be productive. Moreover, challenging problems with such properties can be profitably used for group work. When students try to understand and support each other’s approaches, they engage more deeply with the material. Comparing and contrasting approaches taken by different students leads to making mathematical connections, and student-to-student conversations provide opportunities for students to produce explanations. This does not diminish the teacher’s role in instruction but expands it. More students are involved in generating and reacting to ideas, giving the teacher more “reach.” (See **Dimension 5, formative assessment**).

Dimension 3, equitable access to key ideas for all students

A central goal for powerful instruction is that each and every student has the opportunity to engage meaningfully and powerfully with important ideas. There may be rich mathematical conversations taking place in a classroom, but if some students are excluded from them, the instruction cannot be considered powerful. The classic report *How schools shortchange girls* (American Association of University Women, 1992) documented, for example, that in STEM classrooms girls were called on less frequently, and that when

they were called on, the kinds of questions they were asked tended to be lower level than the questions posed to boys. There are comparable issues regarding all demographic groups. Although there are no surefire approaches to equitable participation, a range of techniques can be used to enfranchise increasing numbers of students. These include the choice of problems, as described in **Dimension 2, cognitive demand and the accessibility of ideas**; creating a context where students feel safe and ideas are refined and built upon rather than simply being critiqued or declared wrong; “revoicing” and supporting the use and refinement of various spoken registers, from everyday to the formal mathematics register; similarly supporting second language use; using tasks that may connect to and build on students’ lives; and carefully employing randomizing devices or “equity tools” that support equitable participation. The social dimensions of equitable participation are addressed in **Dimension 4, opportunities for students to develop productive belief systems, a sense of mathematical agency, and positive mathematical identities**.

Dimension 4, opportunities for students to develop productive belief systems, a sense of mathematical agency, and positive mathematical identities

The curriculum and its implementation play large roles in shaping students’ beliefs regarding the nature of mathematics. Students who experience mathematics in a purely procedural way are likely to develop the understanding that mathematics is dull and mechanical, while students who get to explore and engage in sensemaking will come to see the discipline in rather different ways. But the curriculum is only a small part of what shapes identity and beliefs about oneself. The issue is, what opportunities do students have to engage in mathematical activity, and how are their efforts greeted in the classroom? Can students relate the curriculum to their own lives? Do they have opportunities to venture ideas? Are those ideas taken up and built upon, and do the students have opportunities to build similarly on others’ ideas? If students are grappling with formal mathematical language, can they express themselves in ways that feel comfortable? Are their ideas revoiced in ways that they see themselves as contributors while at the same time their capacity to produce mathematical arguments, and to use formal mathematical language, is being enhanced?

All classrooms are fundamentally social environments. Whom the teacher calls on, in what ways, and how students in small groups position each other, are the mirrors through which students see themselves reflected. Those who are treated as meaningful contributors to the class’s mathematical work are much more likely to see themselves in a mathematically positive light than those who do not. They are more likely to develop productive mathematical dispositions, including a sense of agency (the willingness to engage with mathematical tasks and to contribute to mathematical discussions), and to develop positive mathematical identities.

Dimension 5, formative assessment

Learning is optimized when activities proceed well along the first four dimensions of the framework: the mathematics in which students engage is rich and powerful; students are engaged in productive struggle; each and every student is engaged in meaningful ways with core content and practices; and engagement with the mathematics, the teacher, and other students provides opportunities for the development of productive beliefs about the discipline and oneself. Working toward these ends demands constant adjustments on the part of the teacher. If a group finds a task too easy, is there an extension or an ancillary task that will challenge them productively? If they are stuck, is there a way of providing scaffolding that enables the students to make progress but does not make things so easy that there is no longer productive struggle? What can be done to re-engage students who have disengaged? What sociomathematical norms are established for productive engagement, and when do they need repair (e.g., when a student’s contributions are rejected or demeaned), and in what ways?

Making such judgments during instruction and modifying tasks or classroom dynamics accordingly is called formative assessment. Formative assessment calls for making student thinking public; it needs to be seen and heard if adjustments are to be made. It calls for discretion in judgment—how long does one let students work unproductively (recovering from mistakes is a good learning experience), and how and when does one intervene, to adjust the level of challenge or the social dynamics? Research indicates that it is not easy for teachers to learn to use the techniques of formative assessment, but that when it is used, student learning increases dramatically (Black and Wiliam, 1998). There do exist support tools for teachers. For example the Formative Assessment Lessons downloadable from the Mathematics Assessment Project website at <https://www.map.mathshell.org/> provide extensive guidance for teachers including detailed lesson plans, lists of misconceptions and other issues students are likely to run into when working the lessons, and suggestions for questions and activities when they do. One should not underestimate the challenges teachers face when they try to move from the more traditional form of presenting students with information to the more open form of supporting students when they are grappling with challenging problems. The research indicates that classroom management can be a challenge at first, and monitoring students can feel overwhelming. It also indicates, however, that teachers can settle into new pedagogical habits, with significant learning gains for their students.

Implications and prospects

The past half-century has witnessed tremendous leaps in researchers’ understandings of mathematical thinking, teaching, and learning. The full spectrum of mathematical understandings (content, practices, and habits of mind; metacognitive behavior; beliefs about mathematics and self, including issues of identity) has been identified, as have the dimensions of learning environments that

support mathematical learning along those lines. Unfortunately, instructional practice lags significantly behind these understandings. While some progress has been made, curricula focus for the most part on content and a small subset of practices: some problem solving, some reasoning, and some collaborative group work. However, many central mathematical practices including abstraction, generalization, and effective metacognitive behavior go largely unaddressed, despite evidence that they can be learned. Assessments tend to reify this problem, in that they too focus largely on content. Structurally problematic practices such as tracking and streaming perpetuate structural inequalities, as do the most subtle but equally pernicious ways in which students are positioned by others, with negative impact on identity and potential opportunity.

Addressing such issues is partly a matter of research, and partly a matter of political will and fiscal investment. Researchers and developers need to work on deeper understandings and more useable tools for teachers—the five dimensions outlined in **Productive learning environments** have yet to be fleshed out in adequate detail. But, enough is known about the issues in this article to provide teachers with much more instructional support than is currently the case. Administrators need to understand these issues, and to implement support structures that help teachers work toward these goals. These are all significant challenges. Notable progress has been made, however, and one hopes to see it continue.

Introduction

The ability to read and write is the backbone of daily functions and learning in contemporary society. Reading and writing involve highly complex workings of the human mind (Huey, 1968) and develop through interactions between individual characteristics (e.g., language and cognitive skills and knowledge) and multiple layers of environment such as the language and literacy environment in the home, formal instruction, and larger systems (e.g., state or national policy; Joshi and Aaron, 2012; Kim, 2020a). In this chapter, I review the knowledge and skills that influence development of reading and writing skills, respectively. This is followed by a review of reading-writing relations and the nature of structural relations among contributing skills, reading, and writing skills, such as hierarchical, interactive, and dynamic relations. Practical implications are also discussed.

Knowledge and skills that influence reading development

Reading comprehension involves visually perceiving letters and words, converting them into speech sounds (decoding), parsing linguistic information, developing initial understanding of propositions based on the given information, and integrating propositions for an accurate and coherent mental representation (see Kintsch, 1988; Snow, 2010 for different levels of mental representations and comprehension). Decoding or word reading skills are absolutely necessary for reading comprehension as reading involves written texts. Word reading processes draw on the knowledge of orthographic symbols (orthographic awareness; e.g., knowledge of alphabet letters and their sounds), speech sounds represented in words (phonological awareness), and morphological structure (morphological awareness; Foorman et al., 2016; National Institute of Child Health and Human Development [NICHD], 2000; Snow et al., 1998).

Writing systems represent oral language in various ways where orthographic symbols represent either speech sounds or meaning (see Kim, 2022a). The vast majority of the writing systems in the world employ an alphabetic writing system where orthographic symbols represent sounds. English is an example of an alphabetic writing system. In English, the Roman alphabet letters are used as orthographic symbols that represent the smallest unit of speech sounds, phonemes. For example, the word *dog* has three letters, *d*, *o*, and *g*, each of which represents associated sounds /d/ /ɔ/ and /g/. The three letters, *dog*, are not a single unit that represents the syllable of /dɔg/ or the meaning of a dog. Various orthographic symbols are used in alphabetic writing systems (e.g., Hangul in Korean, Cyrillic in Russia and other countries), but the principle is the same. Orthographic symbols do not always represent phonemes. In Japanese Hiragana and Fidel in Ethiopia, orthographic symbols represent syllables. For example, < in Hiragana represents the /ku/ syllable, and is not a combination of two parts that respectively represent /k/ and /u/ phonemes. In contrast to alphabetic writing systems, Chinese has a meaning-based writing system, called a morphosyllabic writing system where each character represents a meaning unit, morpheme, and a sound unit, syllable, simultaneously (see DeFrancis, 1984 for details about the Chinese writing system).

In languages with alphabetic writing systems, learners need to know orthographic symbols and their associated sounds (orthographic awareness; e.g., letter *d* represents /d/). Learners also need to develop an understanding of the sound structure of a language, phonological awareness, because sounds map onto graphemes (letters or groups of letters). Essentially, learners need to develop an understanding of the alphabetic principle (orthographic symbols represent speech sounds) and grapheme-sound correspondences (mapping of letters or combinations of letters to sounds). Learners also need to understand morphemes and their representation in spelling. Morphemes are the smallest unit of meaning, such as plural *-s* (e.g., *dogs*) and affixes (e.g., *un-* [*undo*]). In many alphabetic writing systems, spellings of words do not represent speech sounds alone, but represent morphological information as well (this is called a morphophonological writing system). For instance, the word *sign* has *g* although it is not pronounced because the word *sign* is morphologically related to *signal*. Meaning information, in addition to phonological information, is preserved in word's spelling. Overlay of meaning on speech sound information frequently causes mismatch between

word's spelling and speech sounds, creating difficulty in decoding and spelling. For example, the words *electric* and *electricity* retain the same spelling *c* despite changes in the sound (/k/ and /s/). Therefore, an understanding of morphological composition of words, morphological awareness, helps word reading and spelling especially for multimorphemic words (Joshi et al., 2008–2009; Kim et al., 2013).

The consistency between graphemes and sounds influences the learning rate of word reading. Word reading acquisition is faster in languages with consistent mappings of graphemes and sounds (transparent orthography; e.g., Finnish, Italian, Spanish) than in languages with inconsistent mappings (opaque orthography; e.g., English). For instance, students learning to read in transparent orthographies reach over 90% accuracy of word reading after 1 year of reading instruction whereas students learning to read in opaque orthographies take 2.5 times longer to reach a similar level of proficiency (Seymour et al., 2003). Writing systems also influence the extent to which word reading and spelling draw on phonology, orthography, and morphology (Katz and Frost, 1992; Kim, 2020a; McBride-Chang et al., 2008; Ziegler and Goswami, 2005). In transparent orthographies, orthographic awareness and phonological awareness are key determiners of word reading and spelling skills whereas in opaque orthographies, morphological awareness plays an important role (e.g., McBride-Chang et al., 2008). Furthermore, in orthographies with high visual complexity (e.g., Chinese), visual processing is of great importance (Zhou et al., 2014).

During the initial phase of word reading development, decoding is a slow process of mapping graphemes to sounds and assembling sounds to pronounce a word. With practice, word reading becomes accurate and rapid, i.e., fluent word reading. Fluent word reading is instantaneous recognition of words as a whole without a slow decomposition process (recognizing a single word instantaneously; Ehri, 2005). It is also important to develop fluent reading of connected texts. This is referred to as text reading fluency or oral reading fluency—the skill to read connected texts accurately and rapidly with expression (NICHD, 2000). Text reading fluency facilitates reading comprehension as the reader is no longer limited or constrained by word reading and thus can focus on understanding the meaning of the text (Jenkins et al., 2003; Kim, 2015a; LaBerge and Samuels, 1974).

While word reading skill is necessary for reading comprehension, it is certainly not sufficient. Comprehension is a highly complex construct and requires an array of knowledge and skills: knowledge of the meanings of individual words (vocabulary) and chunks of words (syntactic knowledge); the ability to reason and infer unstated information (inference), monitor one's own understanding (comprehension monitoring), and employ appropriate comprehension strategies; knowledge of a given topic (topic knowledge); knowledge of discourse features (e.g., text structure); and domain-general cognitive abilities such as working memory and attentional control (see Cain and Oakhill, 2007; Kim, 2020a,b). Reading skills also interact with social-emotional aspects toward reading (e.g., attitude, motivation, anxiety; Kim, 2020a,b), and text features (Francis et al., 2018; Kim, 2020a,b). Reasoning and inference are broad constructs that include multiple aspects and types. For example, inference includes inferring spatial relations among entities, referents of nouns and pronouns, causal structure of propositions, and understanding perspectives (characters', authors', and the reader's own perspective; Graesser et al., 1994; Kim, 2020a,b; Shanahan et al., 2010). Texts in general do not explicitly state all necessary information for comprehension, and therefore, inferring unstated information is part and parcel of establishing coherent understanding of text.

A vital point that is often not well recognized is that comprehension skills initially develop in the oral language context (listening comprehension) and continue to develop in the written language context (reading comprehension). Listening comprehension is a skill to comprehend oral texts, such as stories, multi-utterance conversations, and oral informational texts (e.g., watching or listening to a segment on life cycles of an animal; Kim, 2015b, 2016; Kim and Pilcher, 2016). The above noted skills and knowledge such as vocabulary, background knowledge, and inference are all utilized in listening comprehension (e.g., Florit et al., 2014; Kendeou et al., 2008; Kim, 2016; Kim and Phillips, 2014; Tompkins et al., 2013) and continue to be used in reading comprehension (e.g., Cain and Oakhill, 2007). Put simply, reading comprehension is listening comprehension with additional word reading processes (Gough and Tunmer, 1986), and word reading and listening comprehension, respectively, involve multiple skills and knowledge described above (see the direct and indirect effects model of reading; Kim, 2017, 2020a,b).

Word reading and its component skills (orthographic, phonological, and morphological knowledge) have a large influence on reading comprehension in the beginning phase of reading development whereas listening comprehension and its associated skills and knowledge (e.g., background knowledge, vocabulary, inference) exert increasing influence as word reading skill develops (Kim, 2020a,b). For example, on average, in lower elementary or primary grades, one's word reading skill primarily determines their reading comprehension (Kim, 2015a; Kim and Wagner, 2015). In contrast, by middle school, listening comprehension skill primarily determines reading comprehension performance for the majority of students (e.g., Adlof et al., 2006). Regardless of grade level, however, for students who struggle with word reading, their inadequate word reading skill limits reading comprehension.

Knowledge and skills that influence writing development

Writing requires something to write about, i.e., idea generation. Generated ideas need to be translated or expressed into words and sentences. Translated ideas then need to be converted to printed words and sentences (encoding or transcription). Drafts are revised for expression, cohesion, and coherence, and edited for writing conventions (Hayes and Flower, 1980). These writing

processes draw on a number of skills and knowledge. Idea generation requires world, topic or content knowledge or reading skills. Translation into words and sentences draws on oral language skills. Appropriate and precise use of words and sentence structures is necessary for conveying thoughts accurately, and this requires oral language skills such as vocabulary, morphosyntactic, and syntactic knowledge (assembling words to construct phrases and sentences). The encoding process requires transcription skills such as spelling and handwriting or keyboarding, which place a large constraint on the writing process (Abbott and Berninger, 1993; Graham et al., 1997; Santangelo and Graham, 2016). Spelling draws on the same skills as does word reading—that is, orthographic awareness, phonological awareness, and morphological awareness (Apel et al., 2012; Kim, 2020a; Kim et al., 2013; NICHD, 2000; Snow et al., 1998). Handwriting or keyboarding requires motor skills and orthographic awareness (Berninger et al., 1992).

A quality written composition is more than an assembly of accurately encoded words and sentences. Sentences and ideas should be semantically related and be arranged in a logical order, and the text as a whole should be globally coherent and aligned with the writer's intended meaning. The writer needs to decide what information to present explicitly versus suggest implicitly, arrange sentences for a logical flow of ideas, and determine how to express and present ideas for the presumed audience and their needs. The writer also needs to monitor one's own writing process and be able to employ necessary strategies (e.g., using graphic organizers for planning, or using a writing checklist; Graham et al., 2012, 2016; Kim, 2020c). All these require higher order cognitive skills, such as reasoning, inferencing, and perspective taking (Kim, 2020c; Kim and Park, 2019). In addition, the writer needs to know and employ genre conventions such as text structure and associated linguistic features. Narrative texts typically include characters, a setting, a series of events, problems, and resolutions. Informational texts have different subtypes such as persuasion, opinion, compare-contrast, and description, and each has its own prototypical structure. Therefore, the writer needs to select the appropriate text structure for a given goal using their discourse knowledge to effectively convey ideas (Kim, 2020c; Kim and Park, 2019) because readers find it difficult to comprehend texts that do not follow conventional structures (Meyer, 1975). The writing process and the component skills that contribute to the writing process also require domain-general cognitive skills such as working memory and attentional control (Kellogg, 1996; Kim and Park, 2019; Kim and Schatschneider, 2017). Furthermore, writing skills interact with socio-emotions toward writing (e.g., motivation, attitude, interest, anxiety, self-concept; Graham et al., 2007).

The relations of component skills to writing change depending on the phase of writing development. In the beginning phase of writing development, transcription skills (spelling, handwriting, keyboarding) severely constrain the writing process, whereas other skills and knowledge (background knowledge, higher order cognitions, oral language skills) increasingly influence written composition as transcription skills develop (Kim and Graham, 2022; Kim and Park, 2019). Furthermore, writing develops from knowledge-telling to knowledge-transforming to knowledge-crafting phases (Bereiter and Scardamalia, 1987; Kellogg, 2008). In the beginning phase of writing development, writers tell what they know (hence, knowledge-telling). Writing during this phase is essentially a process of retrieving knowledge from long-term memory and transcribing it into a written product. In the knowledge-transforming phase, writing reflects the writer's thought process and "becomes a way of actively constituting knowledge representations in long-term memory" (Kellogg, 2008, p. 7). The knowledge-crafting phase is when professional expertise in writing is achieved. In this phase, the writer coordinates author, text, and reader representations and crafts writing with the potential reader in mind.

Reading and writing relations

A robust body of literature indicates that reading and writing are not independent, but instead they are related. A recent meta-analysis found that word reading and spelling are strongly related ($r = 0.82$) and that reading comprehension and written composition are moderately related ($r = 0.48$; Kim et al., 2022). One potential reason for reading-writing relations is that many tasks and activities require use of reading and writing skills simultaneously (e.g., writing a book report, writing a grocery list and reading it), and therefore, reading and writing skills are functionally related (Langer and Applebee, 1987; Shanahan, 2016). Another explanation for reading-writing relations is that reading and writing draw on shared skills and knowledge. In other words, highly similar skills and knowledge underlie reading and writing, and consequently reading and writing are related. A heuristic representation of this idea is illustrated in Fig. 1: Reading and writing skills may appear distinct at the surface; however, they are products supported by shared underlying language and cognitive skills that may not be readily visible (Kim, 2020d).

The idea that reading and writing are built on highly similar skills and knowledge was described in the shared knowledge hypothesis (Fitzgerald and Shanahan, 2000). According to Fitzgerald and Shanahan (2000), shared knowledge between reading and writing include (a) metaknowledge about functions and purposes of reading and writing, monitoring one's own meaning-making and word identification or production strategies, and monitoring one's own knowledge; (b) domain knowledge about substance and content, which includes vocabulary and meaning created through context of connected text; (c) knowledge about universal text attributes, including graphophonics (phonological awareness, grapheme awareness, and morphology), syntax (syntax of sentences and punctuation), text format (text structure, and organization); and (d) procedural knowledge and skill to negotiate reading and writing, such as knowing how to access, use, and generate knowledge, and smoothly instantiate various processes.

Fig. 1 A heuristic for reading-writing relations and their shared language and cognitive skills. Reproduced from Kim (2020d).

Fig. 2 Interactive dynamic literacy model. Reproduced from Kim (2020d).

The shared knowledge hypothesis was recently expanded in the interactive dynamic literacy model (Kim, 2020d). Fig. 2 shows details on the shared language and cognitive skills and knowledge as well as the nature of their relations according to the interactive dynamic literacy model (Kim, 2020d). Reading comprehension and written composition are both discourse-level literacy skills, built on lexical literacy skills (word reading and spelling) and handwriting/keyboarding, oral language skills (vocabulary, grammatical knowledge, and discourse language skills), higher order cognition and regulation, and background knowledge. All these are built on domain-general cognition or executive function. Reading and writing skills also interact with socio-emotions toward reading and writing.

The interactive dynamic literacy model has four hypotheses regarding the nature of relations. The first hypothesis is that the skills and knowledge that contribute to reading and writing skills (component skills) have hierarchical relations. According to this hypothesis, the component skills do not have a flat structure where every skill and knowledge is directly related to reading comprehension and written composition. Instead, there are multiple layers of higher order and lower order skills, and lower order skills support higher order skills in a systematic and cascaded way, resulting in multiple chains of relations. For example, domain-general cognition supports phonological, orthographic, and morphological awareness, which, in turn, support lexical literacy skills (word reading and spelling) and handwriting/keyboarding skills, which support reading comprehension and written composition. Domain-general cognition also supports vocabulary and grammatical knowledge (morphosyntactic and syntactic knowledge),

which, in turn, support higher order cognition and regulation, which support discourse oral language skills (e.g., listening comprehension, oral composition, retell), which, in turn, support reading comprehension and written composition (see Fig. 2). The hierarchical relations hypothesis entails a series of interconnected relations among skills such that the numerous language and cognitive skills and knowledge are directly “and” indirectly related to reading comprehension and written composition. Therefore, once higher order skills are accounted for, the direct relations of lower order skills to reading comprehension and written composition are reduced (in the case of partial mediation by higher order skills) or disappear (in the case of full mediation by higher order skills). For example, if a statistical model includes working memory, vocabulary, and listening comprehension as predictors of reading comprehension, working memory and vocabulary would not directly predict reading comprehension because their contributions are captured by listening comprehension, a higher order skill, as long as listening comprehension is adequately measured (i.e., the vocabulary and working memory demands of listening comprehension tasks and reading comprehension tasks do not vastly differ; see Kim, 2020b, 2022b for further details).

The second hypothesis of the interactive dynamic literacy model is that reading and writing skills as well as their component skills develop interactively, influencing each other (i.e., interactive relations hypothesis; Kim, 2020d). The interactive relations are mediated by learning experience and practice. Reading and writing have bidirectional relations (Ahmed et al., 2014; Shanahan and Lomax, 1986), and reading experience supports writing skills, and writing experience supports reading skills (Graham et al., 2018). For example, reading texts helps individuals recognize and learn text structures, linguistic features, and authors’ purpose and intent, all of which support writing texts; the experience of writing texts also helps individuals understand these aspects, which, in turn, supports reading comprehension (Graham and Hebert, 2010). Word reading experience leaves orthographic, phonological, and morphological traces in memory, which supports spelling development, and the same applies to the experience of spelling words for word reading development. Similarly, vocabulary knowledge supports reading comprehension, and students with better reading comprehension tends to read a greater amount of texts than students who struggle with reading, which leads to greater exposure of vocabulary, which leads to better reading comprehension. Successes or failures of reading and writing experiences trigger one’s socio-emotions toward reading and writing, which, in turn, support or inhibit the development of reading and writing skills, which further leads to socio-emotions toward reading and writing.

Interactive relations implicate virtuous and vicious cycles of development of reading and writing skills, and their component skills. This hypothesis is akin to the Matthew Effects hypothesis in learning—the rich get richer, and the poor get poorer (Stanovich, 1986). Initial skill level is critical to setting off the cycle, and therefore, supporting development of foundational skills is crucial for successful reading and writing development. Also critical is continuous support for reading and writing development and their component skills with sustained instruction and opportunities for practice as learning experiences and practice are key to promoting the virtuous cycle and breaking the vicious cycle.

The third hypothesis of the interactive dynamic literacy model is that reading and writing difficulties co-occur (Kim, 2020d). If reading and writing are related and they rely on largely the same resources, success or difficulties with reading and writing development likely co-occur. Those who experience difficulties in reading will likely experience difficulties in writing, and vice versa (e.g., Graham et al., 2021). Furthermore, aligned with the hierarchical relations hypothesis, difficulties with reading and writing co-occur with weaknesses in oral language and cognitive skills. That is, those who have a weak foundation in oral language skills (including those with developmental language disorder) likely experience weak reading and writing skills (Berninger et al., 2015; Carretti et al., 2016; Catts et al., 1999; Dockrell and Connelly, 2015; Fey et al., 2004; Graham et al., 2020). Those who have weak skills in lexical literacy skills (word reading and spelling), including those with dyslexia, also experience difficulties in reading comprehension and written composition (Berninger and May, 2011; Berninger et al., 2008; Botting, 2007; Catts et al., 2005). Those who have weak higher order cognitions (e.g., inference or perspective taking) also experience difficulties in comprehension (Cain and Oakhill, 2007) and composition (Kim, 2020c; Kim and Park, 2019). Those who have weaknesses in working memory or attentional control are vulnerable to weaknesses in language and cognitive skills, and consequently in reading comprehension and written composition (Berninger, 2008; Kim, 2020b,c).

The last hypothesis is dynamic relations: reading-writing relations differ due to the development of reading and writing skills, grain size of reading and writing, and tasks and measurement (Kim, 2020d). Dynamic relations as a function of development refer to differential roles of component skills to reading and writing skills depending on the developmental phase of lexical literacy skills (word reading, transcription). In the beginning phase, lexical literacy skills have a large influence on discourse literacy skills. Development of lexical literacy skills reduces its constraining role, and permits oral language, background knowledge, and higher order cognitions to play greater roles in reading comprehension and written composition (Kim, 2020b; Kim and Graham, 2022).

The strength of reading-writing relations also differs as a function of grain size: The relation is stronger between word reading and spelling than between reading comprehension and written composition. Indeed, evidence indicates that word reading and spelling are very strongly related whereas reading comprehension and written composition are moderately related (Kim et al., 2022). The differential strength of reading-writing relations has implications for the occurrence of reading-writing difficulties. The strong relation between word reading and spelling implies that individuals who struggle with word reading are highly likely to experience difficulties with spelling, and those who struggle with spelling are highly likely to experience difficulties with word reading. The moderate relation between reading comprehension and written composition implies that although strong readers tend to be strong writers, there will be more divergent cases—skilled readers may not necessarily be strong writers (Kim, 2020d).

Word reading and spelling are strongly related because they essentially involve the same processes of retrieval of graphemes and their associated phonological (and morphological) information. Although the sequence of processes involved in word reading and spelling is opposite—word reading involves retrieving letters and graphemes and their associated phonological (and morphological) information, selecting appropriate grapheme-sound correspondences, and assembling them, whereas spelling involves retrieving accurate phonological (and morphological) information, mapping them with graphemes, and assembling and writing graphemes in correct order (Ehri, 1997; Kim, 2022a)—word reading and spelling rely on the same constrained set of skills: phonological, orthographic, and morphological awareness.

Compared to word reading and spelling, reading comprehension and written composition involve considerably divergent processes although they both involve meaning-making processes and draw on highly similar skills and knowledge. In reading comprehension, the text is given to readers and therefore, the extent of meaning-making is delimited by the given text (Kim, 2020d; Langer, 1986; Langer and Flihan, 2000). In written composition, the writer has to create a text, and therefore, the idea generation delimits the subsequent writing process. Let's take an example of reading versus writing a recipe. When reading a recipe, one needs to decode, understand each proposition, and develop a mental model of the cooking sequence. When writing a recipe, one has to know and select a recipe to write about, think about necessary materials (ingredients, tools) and the organization of each step, think about how to express each step by selecting vocabulary and sentence structures, and consider readers' needs (what units of measurement to use, whether to use images such as pictures for which steps, how much detail to provide, and what style of language and organization to use). This illustration clearly shows that writing a recipe requires more than knowing or comprehending a recipe. It requires extensive planning and critical thinking to a much greater extent than reading a recipe. In other words, although both reading comprehension and written composition draw on highly similar skills and knowledge, the skills and knowledge are differentially tapped during reading and writing processes.

The relation between reading and writing, particularly between reading comprehension and written composition, is also expected to differ depending on the dimension of writing—reading comprehension is more strongly related to writing quality than writing productivity (Kim and Graham, 2022; Kim et al., 2022). Written composition is evaluated in multiple ways. For instance, quality of overall writing, the presumed outcome in written composition, typically evaluates quality of ideas, organization, word choice, sentence structures, voice, spelling, and punctuation. Measures beyond writing quality are also widely used in the field, particularly for developing writers, including writing productivity (amount of written text; Anderson, 1988; Kim et al., 2015), writing fluency ("efficiency and automaticity in writing connected texts"; Kim et al., 2018, p. 322), or curriculum-based writing indicators (CBM writing; e.g., correct minus incorrect word sequence; Graham et al., 2011; Kim et al., 2015; McMaster and Espin, 2007). While these indicators are not the ultimate goal of written composition, they are used as indicators of writing quality for developing writers as they are reliable, have high utility for progress monitoring purposes, and are moderately to strongly related to writing quality for developing writers (Kim et al., 2015; Kim and Graham, 2022). However, the extent to which writing quality, writing productivity, writing fluency, and CBM writing draw on language and cognitive skills differs. Writing quality draws on all the skills shown in Fig. 2 whereas writing productivity and writing fluency are strongly influenced by transcription skills, and CBM writing is strongly influenced by one's grammatical and spelling skills (Kim et al., 2014, 2015; Kim and Graham, 2022). Given the multi-dimensional nature of written composition, the magnitude of the relation between written composition and reading comprehension varies depending on the focal dimension of written composition (Kim and Graham, 2022; also see Kim, 2022b; Francis et al., 2006 for a discussion of measurement of reading comprehension).

Reading-writing relations are also expected to vary depending on tasks. Reading and writing are used in a variety of tasks for different goals, and different tasks differentially tap skills. For example, reading a recipe to prepare dinner versus reading about World War II for a class project would not require the same extent of language and cognitive skills. Similarly, higher order cognitions are differentially needed for writing a short recount of a weekend activity versus writing a book report elaborating on motivations and behaviors of multiple characters. Depending on the nature of the tasks and goals, readers and writers draw on skills and knowledge differentially (Kim, 2020a,b; Kim and Graham, 2022).

Implications

Reading and writing skills as well as their component skills develop interacting with environments. One prominent environment that has a direct impact on reading and writing development is formal instruction. Variation in quality of instruction makes a difference in students' reading and writing development (e.g., Connor et al., 2013; Gersten et al., 2010; Kelcey and Carlisle, 2013). Theoretical models and evidence reviewed above imply that component skills of reading and writing development need to be systematically and explicitly taught. For example, for word reading and spelling development, orthographic symbols and their associated sounds, phonological compositions of words, and morphological structures need to be taught. Unlike oral language skills, reading and writing skills do not develop "naturally" (Rayner et al., 2001), and cracking the code requires explicit and systematic instruction for the majority of learners (e.g., Foorman et al., 2016; Graham and Santangelo, 2014; NICHD, 2000; Snow et al., 1998). Instruction should also target oral language skills and higher order cognitions, and support building background knowledge as early as possible. "Natural" development does not discount the importance of environmental input—although individuals develop oral language skills as long as language experience is present, linguistic environment has considerable influence on language development (e.g., Hart and Risley, 1995). Vocabulary tends to receive instructional attention when it comes to oral language skill, but oral language skill is a much larger construct, which includes syntax or sentence structures and discourse skills (e.g., listening

comprehension, oral retell and composition; Kim, 2016, 2020a). Higher order cognitions such as inference are often taught in the context of reading comprehension when students have developed word reading skills. However, higher order cognitive skills develop and should be also fostered in the oral language context before reading skills develop.

The hierarchical nature of relations indicates that instruction should be systematic considering the chain of interconnections (Kim, 2020b, 2022b). For instance, fluent word reading and spelling skills are needed to free cognitive resources for higher order thinking processes. Interactive relations indicate that integrated instruction of reading and writing, in addition to instruction that focuses on reading and writing respectively, will result in a synergistic effect that maximizes reading and writing development (Graham, 2021; Kim, 2020d). The hypothesis of co-occurrence of reading-writing difficulties implies a need for attending to reading and writing skills together in identifying and addressing students' needs. For example, for individuals with dyslexia, it is important to consider and address difficulties not only in reading, but also in writing. Similarly, for individuals with writing difficulties (including those with dysgraphia), difficulties in reading should be assessed and addressed (Kim, 2020d).

Lastly, the complex and multi-dimensional nature of reading comprehension and written composition suggests a need for a thoughtful approach to measuring reading comprehension and written composition, and a need for taking this into consideration in assessment and instruction. For example, it is important to use multiple tasks to measure reading comprehension and written composition skills precisely, especially for high-stakes decisions (e.g., determining one's eligibility to school-based services; e.g., Francis et al., 2006; Kim et al., 2017).

Introduction

Learning science is hard. Such a statement automatically invites the question of why science is any harder than any other subject—a not unreasonable response. Yet, I will argue that there are somethings about the sciences that make developing any understanding harder than most, if not all other subjects. Some of these reasons are intrinsic to the nature of the sciences and some of them are extrinsic to the way the sciences are framed and the way they are taught.

At a very basic level, there is the commonsense test. If you were to wonder into an undergraduate chemistry lecture, confronted with symbols, mathematics and charts, most of us would be at a loss to understand what was being discussed. In contrast, wondering into a humanities lecture, most of us would at least be able to understand the gist of what was being discussed. What this points to is that one of the challenges of learning science is learning a language—essentially the challenge of acquiring the languages of the discipline and becoming disciplinary literate (Shanahan and Shanahan, 2008). And the plural “languages” is used because words alone are insufficient to communicate meaning in science. Rather, as well as words, science relies on charts, symbols, mathematics, diagrams and pictures to communicate meaning.

Why this is so is obvious if you think for a moment about how difficult it would be to explain the workings of the heart using words alone. Hence, the language of science is multi-semiotic or multi-modal (Kress et al., 1998; Kress and Van Leeuwen, 2001; Lemke, 1998; Martin, 1998).

To start, it helps to define what I mean by “science”. First, as the reader will note from the title, I would argue that there is no singular science. Rather there is a diversity of activities which share a common goal of seeking to answer three questions about the material world (Ogborn, 1988; Osborne, 2011). These are:

1. What exists? What philosophers call the ontic question
2. What causes this event/phenomenon to happen? The causal question
3. How do we know? The epistemic question

In addition, scientific knowledge invites two other questions:

4. How do we talk about this phenomenon/explanation? The communicative question
5. What can we do with this knowledge? The technological question

The sciences are also defined by their use of a set of distinctive “styles of reasoning” (Crombie, 1994; Hacking, 1992; Kind and Osborne, 2017). These are Mathematical Deduction, Experimental Exploration, Hypothetical Modeling, Categorization and Classification, Probabilistic Reasoning and Historical-Based Evolutionary Reasoning. In doing so the sciences use a mix of deductive mathematical and logical arguments such as those used in the derivation of Newton’s Laws; inductive generalizations represented by the laws of conservation of energy and conservation of momentum; and abductive arguments which are inferences to the best explanation (e.g., theory of evolution, origin of the continents). However, which of these is the focus depends on which science you are engaged in. The plant taxonomist is clearly concerned with categorization and classification while the astrophysicist working in cosmology relies much more on developing theoretical arguments for the evolution of the universe, stars and other celestial objects. In short, all the sciences really share is a common epistemic focus represented by the three questions above.

The fact that there is such diversity in the sciences points to the first difficulty and challenge of learning any science—there is simply an enormous amount of knowledge to be learned or acquired, more than any mere mortal can acquire in a lifetime. This invites the question of which science to start with and, more importantly, which end of the telescope? Do you, for instance, begin by building the foundational bricks and let the picture of the edifice emerge over time or, alternatively, do you present a picture of the edifice and worry less about presenting a picture of how it was built? As for which science should be taught in school, in reality there is little choice as what is offered is a product of tradition and embedded institutionalization. For instance, a good argument could be made that environmental science is more important than physics, chemistry, or biology. However, the facilities and the teachers to teach it do not exist so—the extant choices persist.

So, what are the challenges to learning any science? In what follows, I will argue that scientific ideas are not simple and straightforward. Rather, there are four specific challenges. First, they are often extraordinary and difficult to believe. Second, the goal of science is to construct models or representations of reality. Doing this often means producing representations of things that we cannot see or are too large to imagine. Third, because of the complexity, it is communicated in a form that is reliant on not just words but a diversity of forms of language—all of which have to be taught and learned but often are not. The final challenge lies in the way the sciences present themselves. As a consequence they do not show themselves in their best light.

Challenge 1: the failure of common sense

To seek to explain is only human. Explanation is supported by a mix of observation and our social interaction with each other. The problem is that relying on observation and common-sense is a poor way to generate scientific understanding. Observation would suggest that day and night are caused by a moving Sun, that the Moon is bigger than the Sun, and that the Earth is flat. Common sense tells you that heavier things fall faster, that you need a force to keep an object in motion, and that air is weightless. School science tells you that the opposite may be true. And observation itself is pretty useless at explaining the structure and function of living organisms, why we get infected with diseases, or why we look like our parents. Common sense ideas are embedded in our language too, as we worry about “letting the cold in” rather than letting the heat out, or we “cast a glance” or “stare daggers” at others which suggests that vision is an active process. And humans are definitely not animals as science would have you believe.

Moreover, common sense and our everyday experience reinforces these ideas such that by the time you arrive in a science classroom as a neophyte student you have already formed a good body of ideas about how the world works. The problem is that most of them are wrong. Scientific ideas, it turns out, are unnatural or uncommon sense (Cromer, 1993; Wolpert, 1992). Rather, the ideas developed by science could be categorized as crazy. Physics, for instance, wishes to tell us that heavier things do not fall faster, that air has mass and that it is possible for constant motion to be sustained without a constant force. When it comes to the atomic scale, science wants to argue that most of the atom is empty space and, at the macroscopic scale, that the Universe is 13 billion years old and created in a big bang.

Biology tells us that diseases are spread by tiny, invisible, living organisms that are pervasive in the air we breathe; that we look like our parents because every cell in our body carries a chemically coded blueprint of how to reproduce ourselves; and that plants are capable of taking carbon dioxide and water and turning them into sugars in their leaves. As for the geological sciences they would have you believe that continents can move! In short, the teacher of science is a teacher of crazy ideas. Few teachers of science recognize this though as so many of these ideas have become scientific commonplaces. Lost is the intellectual achievement they represent. And, as many a scientist might say, for good reasons. Science is a prospective discipline. What matters is creating new knowledge not celebrating the achievements of yesteryear. Once consensus has been achieved, science moves on and the struggles that were required to achieve this hard won knowledge are too often forgotten and remain untold (Matthews, 2015; Monk and Osborne, 1997). Yet, the lack of history, the lack of a story about the intellectual and creative struggle robs the teaching of science of any account of the cultural achievement it represents. It removes the human dimension, the social context and an important element of awe and wonder at the minds that were able to solve great intellectual challenges. Such awe and wonder are an important element of engagement for many young people (Gottlieb et al., 2018; Hadzigeorgiou, 2012).

More fundamentally for the learning science it also poses another problem. The extensive research carried out from a constructivist perspective on young children’s understanding of science shows conclusively that young people do not arrive in the classroom as *tabula rasa* (Black and Lucas, 1993; Driver et al., 1985; Osborne and Freyberg, 1985; Pfundt and Duit, 1994). And, given that it is well-established that we make sense of new ideas drawing on our existing background knowledge (Ausubel, 1968; Chi, 2009; Osborne and Wittrock, 1985), when the young student is confronted with an idea that differs significantly from their pre-existing conceptions, learning the new idea requires a substantial act of mental accommodation and transformation. In short, it takes time, reflection and exploration of the new idea and direct instruction is, not surprisingly, highly ineffective (Chi, 2009; Hake, 1998; Kuhn, 2007). Rather, the teaching of science must be seen as a conversation which begins with the teacher asking the student how they see the world, and then the teacher responding with their strange and unfamiliar version. “So”, you can imagine, the teacher saying, “you think the Earth is flat. I can understand why. It looks flat. But I have a strange idea to tell you. It only looks flat at your scale. If you go out, it is actually curved. Here is my argument to convince you ...”. Research shows that teachers who begin teaching this way have students who learn more effectively (Sadler et al., 2013). Likewise, texts that explain why the common misconception is flawed, as well as explaining why the scientific idea is correct, produce significantly better

learning outcomes (Guzetti et al., 1997; Sinatra and Broughton, 2011). Ausubel's famous mantra that "If I had to reduce all of educational psychology to just one principle, I would say this: The most important single factor influencing learning is what the learner already knows. Ascertain this and teach him accordingly" is as true today as when it was first written (Ausubel, 1968).

Challenge 2: abstraction

However, there is another challenge embedded in the conversation required to learn science. This is, as Rom Harré has pointed out, is that a scientific conversation is really about three types of entities. These are:

- The macroscopic things that surround us, both living and non-living
- The microscopic or invisible elements that we cannot see such as particles, germs or the insides of our bodies and the macroscopic entities which are too large to imagine such as a continent, the solar system, or the Universe
- The theoretical which are unobservable even with instrumentation—Quarks, Higgs Boson, strings (Harré, 1986).

At the macroscopic level, the referents are concrete and easily observable. This is why so much of the focus of elementary science is on living things and on introducing a way of categorizing and classifying such entities. What is the difference between living and non-living? What objects float and which ones sink? What are the phases of the Moon and how do they vary? Until such entities have been identified and labeled, we have no way of talking about them (Bowker and Leigh Star, 1999).

The challenge begins when the conversation moves to discussing anything that is not observable such as the workings of the human body or, alternatively, a new abstract concept such as force, speed, or an electric current. The only way we can talk about things we cannot see is by constructing models (Gilbert and Justi, 2016; Johnson-Laird, 1985; Nercessian, 2008). Some of these are physical models which bear a close similarity to the actual thing—such as skeletal or anatomical models of the heart, eye and other organs. Some, however, are more removed such as the models we enact to explain how day and night occurs, particle models of the air to explain how scent crosses a room, the various models of how electricity flows, or the Bohr model of the atom.

Models are not veridical accounts of nature. A moment's consideration of the Bohr model of the atom identifies numerous flaws (the electrons are far too large, the electrons are much further away, the nuclei are not colored and so on). Rather they are tools which are "true enough" that enable us to reason about the material worlds. They are essentially "felicitous falsehoods" (Elgin, 2017) whose aim is "to come up with a representation that affords an understanding of the phenomena, not one that replicates the phenomena."

However, such models are mentally challenging to the young mind which prefers concrete referents. For, despite the many arguments that have surrounded the work of Piaget (Adey and Shayer, 1990; Metz, 1995), it is impossible to escape the conclusion that the young child's brain is different from the adult, and that the young child thinks differently (Dehaene, 2020). During adolescence, we are in the process of building neural networks and strengthening the neural network that is the basis of our cognitive capabilities. Learning to think with a model requires intellectual effort and active processing. It is challenging. Challenging tasks need support and time to practice. The British project "Cognitive Acceleration through Science Education" was one approach that took this idea seriously with results that showed significant gains for the experimental group (Adey, 1992; Adey and Shayer, 1994).

In addition to models, there is also the fact that many of the abstractions employed by science such as force, acceleration, density, heat, and power have both no concrete referent and are often ratios. For instance, explaining why it is important to keep young babies wrapped up well requires an understanding of the ratio of surface area to volume of any object. And while velocity or speed are a ratio of distance per unit of time, acceleration is a ratio of a ratio! Moreover, many of the models constructed by science idealize the entities so we talk of point masses, ideal gases and genes in a manner that belies the reality that surrounds us. Getting your mind around these is hard, intellectual work. Not for nothing did Sylvia Plath write of her early experience of physics education that:

The day I went into the physics class it was death. A short dark man with a high lisping voice, named Mr. Manzi, stood in front of the class in a tight blue suit holding a little wooden ball. He put the ball on a steep grooved slide and let it run down to the bottom. Then he started talking about let a equal acceleration and let t equal time and suddenly he was scribbling letters and numbers and equals signs all over the blackboard and my mind went dead.

Plath (1966, p. 36).

Indeed, the mathematics Sylvia Plath experienced is an example of the Harré's third realm—the theoretical which we represent with mathematics. Mathematics is an integral part of science and unavoidable. However, its abstract nature and distance from any common macroscopic referent makes it difficult for many students to understand.

Challenge 3: learning the languages of science

One of the major challenges of science, however, is that the sciences are reliant on a multi-semiotic mode of communication. As Lemke argues:

Science does not speak of the world in the language of words alone, and in many cases it simply *cannot* do so. The natural language of science is a synergistic integration of words, diagrams, pictures, graphs, maps, equations, tables, charts, and other forms of visual mathematical expression.

Lemke (1998).

Clearly the sciences make extensive use of technical vocabulary. Moreover, sentences are written in a dense prose often using the passive voice and they are accompanied by many diagrams, charts and figures that are essential to understanding the meaning of the text. But why is this? Must it be so? The answer is an unequivocal yes. In all contexts, language evolves to be as efficient as possible in communicating meaning. The consequence is a development of a professional language that is only understood by those who have been inducted into the meaning of the terms and how to use them appropriately. This is as true for a group of lawyers, doctors or architects as it is for scientists. This view of language, which goes under the name of systemic functional linguistics, is that:

Technical language has evolved in order to classify, decompose and explain. The major scientific genres—report, explanation and experiment—have evolved to structure texts which document a scientist's world view. The functionality of these genres and the technicality they contain cannot be avoided; it has to be dealt with. To deal with it, teachers need an understanding of the structure of the genres and the grammar of technicality Ways must be devised to provide access to this technology. And the answer must not be watering the technology down.

Halliday and Martin (1993).

What then are the features of this technical language that make it so difficult? Knowing what those challenges are is a vital element of the knowledge of the professional science educator if they are to help their students learn from such texts. In summary, they are:

Lexical density

The most recognized feature of informational science texts is their sheer quantity of information or lexical density (Halliday and Martin, 1993). Lexical density refers to the number of content words within a text and how much information is in the text. The consequence is that the cognitive demand of constructing meaning from science texts is such that it cannot be comprehended in one pass. Rather, the reader must break, annotate, and reflect to construct meaning (Davies and Greene, 1984). More than anything else, lexical density is the major distinction between narrative and informational texts.

Vocabulary & Academic language

Informational science texts are lexically dense using both technical vocabulary and academic language extensively (Pearson et al., 2010; Snow, 2010; Wellington and Osborne, 2001). Technical vocabulary are words that have a specific meaning within a discipline, while academic language refers to words that are encountered in academic discourse but are not specific to any discipline. Indeed, the quantity of words encountered in a high school science course can exceed that introduced in learning a foreign language (Merzyn, 1987). One of the fundamental difficulties in teaching the sciences is the common perception that it is reliant on a technical vocabulary of words which are unfamiliar to the uninitiated. Yet as study after study has shown, while the technical words do naturally cause difficulty with comprehension, it is the non-technical but unfamiliar words—in short words that are used in academic English or academic words like “abundant”, “linear”, “diversity”, “stimulate” and more that students find just as difficult to comprehend (Farrell and Ventura, 1998; Marshall et al., 1991; Pickersgill and Lock, 1991; Snow, 2010).

Another feature of academic language is the use of the passive tense. As Snow points out, “in everyday language most sentences begin with pronouns or animate subjects; verbs refer to actions rather than relations; and long sentences are characterized by sequencing of information rather than embeddings” (2010, p. 450). But what of the sciences? Here, the personal is excised and students are encouraged to write in the passive voice. So rather than writing “we took the Bunsen burner and heated the copper sulfate”, the standard genre of science would use the wording “the copper sulfate was heated” resulting in the excision of any sense of an actor or the personal. Similarly, reports or explanations in the sciences tend to remove the agents, the scene, the motives, and any sense of temporality. The argument for this approach in the sciences is that it is the object that is the primary feature of interest rather than what is done to it (Wellington and Osborne, 2001). Maintaining the impersonal authoritative stance, however, creates a distanced tone that is often puzzling to adolescent readers and is extremely difficult for adolescents to emulate in writing.

Logical connectives

Logical connectives are words that combine two sentences or statements (e.g., therefore, so, thus). Logical connectives are essential to the process of constructing an argument, generating the relationships between claims, warrants, and data, and a means of contrasting and comparing phenomena (Fang, 2008; Gardner, 1977; Halliday and Martin, 1993). In science they are vital to express causality—how one thing follows from another. Commonly, however, connectives are excised from science texts to improve readability by shortening sentences even though struggling readers benefit from more explicit texts (i.e., the ones that contain more connectives) and readers benefit from adding explicit connectives to increase inferential processing (Ainsworth and Burcham, 2007; O'Reilly and McNamara, 2007; Roman et al., 2006).

Polysemy or Ambiguity of Meaning

Polysemy refers to the existence of multiple meanings for a single word or phrase. Many research studies have shown that all students have considerable difficulty determining the appropriate meaning of a word in different contexts (Cassels and Johnstone, 1985; Pickersgill and Lock, 1991). Scientists would like their words to be a purely technical sign with no index of meanings. However, this can never occur because words can never be detached from their context of use (Wittgenstein, 1953). As Montgomery (1996) points out, “perceiving any word as exclusively technical—any word, above all that has long been used in other forms of discourse—can only come about from a socialized practice of reading, one that relies in the end on a kind of trained blindness (p. 46).” This is particularly true of words which are used in the sciences with one meaning and in everyday discourse with another meaning—words such as force, power, theory, excite and more.

Nominalizations

A nominalization is a verbal description of a process that is converted into a noun (e.g., the process of cutting down the forest is referred to as “deforestation”). Nominalizations allow complex ideas to be expressed with the minimal use of language (Halliday and Martin, 1993). In scientific journals, one in seven nouns is a nominalization (Holtz, 2009). Nominalization removes human agency, as in the example above, we no longer know who conducted the deforestation; and the process becomes an abstraction, making it harder to conceptualize (Schlepppegrell, 2004; Unsworth, 1999). Typical examples might be “the rate of engine failure” rather than writing “the rate at which engines fail” or “glass crack rate” rather than “the rate at which a glass crack grows”. In both of these examples, the verb has been converted into a noun. The sciences abound with such words—condensation, absorption, scattering, reduction, transmission are examples of words which are derived from nouns and used because they are functionally effective at capturing a process with the minimum number of words. But while a scientist might say “The grid supports the transmission of electricity” for a 9-year-old child, we would write “The grid is how electricity is transmitted”. The use of the verb reduces the grammatical complexity and is more akin to how young children learn to talk. Thus, the common use of nominalizations in science texts makes them unfamiliar and difficult for young children to read.

Multimodality

Natural language is very limited in its ability to describe continuous variation, shape, and the interrelationships of structure, form, and function. Indeed, as Lemke argues, often it *cannot* do so (Lemke, 1998). To achieve this goal, the sciences depends on a synergy of semiotic signs—symbols to represent elements; quantities and units to represent amounts; graphs and charts to summarize relationships, frequencies, and patterns; tables to summarize numerical data; and mathematics to express relationships (Kress et al., 2001; Lemke, 1998; O’Halloran, 2011). That these are all interdependent can be seen from a cursory examination of any contemporary scientific paper. Temporarily excising one of these components makes the process of constructing its meaning significantly harder, if not impossible. Thus, multimodality is the combination of two or more symbolic systems of meanings and the sciences do not speak of the world in the language of words alone, and in many cases they simply cannot do so.

Visualizations

Increasingly, ideas in the sciences are communicated through static or dynamic visualizations. That is, visualizations are representations of an object, situation, or set of information as a chart or other image. Contrary to the common perception that these facilitate communication, students often have difficulty in understanding and interpreting such representations (O’Toole, 2004; Phillips et al., 2010; Zhang and Linn, 2011). Thus, contrary to the idea that a diagram, chart or computer visualization might make it easier to understand, the opposite is often true.

For instance, consider the common standard diagram of the heart. Imagine if you will, how difficult it would be to describe this organ to another without the use of diagrammatic representation. Likewise, many other phenomena and their patterns of interaction are best described in the language of mathematics, which becomes a bridge between verbal language and the meaning scientists seek to express. So complex are some of the concepts and ideas that the sciences wish to communicate that they cannot be communicated with words. The modern theoretical physicist often speaks a language heavily dependent on mathematics. Thus, the task confronting the student is not one of learning the language of science but one of learning the *languages* of the sciences.

Moreover, the language of the sciences is exceptional in that its discourse is cumulative. This does not mean that it contains some inner hierarchy but merely that each conversation in any given scientific domain builds on ones that have gone before; the science thus progresses in a fundamental way that most other disciplines do not (Tallis, 1995). The consequence is that the discourse of the sciences increasingly deviates from that of other discourses. Compare, for instance, the writings of any 19th century introduction to gravitational theory with any contemporary text on gravity with its matrix mathematics, tensor calculus and more. The two are virtually incommensurable. For the neophyte student the multimodality of the sciences is an additional barrier to entry, extending the period of apprenticeship and learning. The issue is that students must be taught how to read and interpret these modes of semiotic communication which are often not straightforward.

Challenge 4: the nature of the curriculum

The final challenge in learning science is the way the sciences present themselves and the nature of the curriculum that frames how it is perceived by many a student. Across the globe, the standard approach is to take a foundationalist approach to curriculum design. Thus, the basic concepts of any topic are introduced first. Students studying physics will learn about force, velocity, speed, and Newton's Laws of Motion without much rationale as to why these might be important or any explanation of the cultural significance. Likewise, in Chemistry, the periodic table is presented as if it were commonplace, with no significance attached to the fact that it is one of the great achievements of the discipline. Photosynthesis will be studied in biology in a mechanistic manner but there will be little recognition of how amazing it is that plants can produce complex sugars from light, carbon dioxide and water in a chemical reaction that we cannot replicate.

Learning science means learning to understand a body of consensually agreed, well-established knowledge. There is no uncertainty about such knowledge. This can be seen in the fact that there is no meta-discourse about the degree of certainty of the nature of the knowledge that is presented. Any "may" or "possibly", as in Rutherford's initial interpretation of the implications of his experiment investigating how alpha particles were scattered by a thin gold foil, is absent. His finding suggested to him that the atom was mainly empty space with a very small dense nucleus. These tentative statements are simply transformed into statements of the form "the atom consist of a small dense nucleus of neutron and protons with electrons orbiting at a distance". In such a manner, hard-won knowledge is transformed into a set of taken-for-granted-facts.

Yet so much of science education has lost sight of that awe. As Dawkins so elegantly puts in his own homage to the sciences, *Unweaving the Rainbow* (Dawkins, 2000):

There is an anaesthetic of familiarity, a sedative of ordinariness which dulls the senses and hides the wonder of existence. For those of us not gifted in poetry, it is at least worthwhile from time to time making an effort to shake off the anaesthetic (p. 6).

Or as Pinker puts it, "[s]cience has provided the world with images of sublime beauty: stroboscopically frozen motion, ... graceful spiral galaxies and diaphanous nebulae ..., and a luminous Planet Earth rising above the moon's horizon" (Pinker, 2018). Moreover, as he points out, it has "granted us the gifts of life, health and wealth" and knowledge which has eradicated diseases such as smallpox which killed 300 million people in the 20th century alone, making the current Covid-19 pandemic look like chump change. Likewise, the development of penicillin reduced the deaths from infectious diseases per year from 90,000 in 1900 to 2300 in 1980 in the UK alone. And if, such knowledge is commonplace, why should it be of interest to the neophyte student?

Thus, laying out such unequivocal and unquestionable bricks of the scientific edifice makes the learning of science hard. As Claude Bernard famously said—"Science is a hall full of awe and wonder, the problem is the long dark kitchen you have to go through to get there." (Bernard, 1957) Students are given no sense of the scientific edifice, the intellectual achievement it represents and the awe and wonder that should be an inherent feature of such a great cultural achievement is simply lost. Associated with this is a lack of any discussion of the epistemology of science. Presented in this manner, students are given the impression that this is the way the world is. There is no acknowledgment that the goal of science is the construction of explanatory models (Lehrer and Schauble, 2006) and that these are not accurate representations. If there is any treatment of the epistemic basis of science it is often reduced to an introductory chapter on "the scientific method" which is (a) philosophically laughable as the methods of science are numerous and diverse (Allchin, 2012; Bauer, 1992; Crombie, 1994), and (b) suggests that all creativity in science is reduceable to the application of a singular algorithm. If this is the nature of scientific work, what is the value in making the effort to learn a body of knowledge which seems to have little relevance to their everyday life or practice?

Yet, science education has a duty to prepare students to evaluate scientifically based arguments. At a minimum that requires the ability to evaluate expertise in science. Essential to this competency is an understanding that science is a communal enterprise, that science is not infallible. In many ways, error is absolutely the norm in the sciences (Allchin, 2012). However, while individual scientists or teams might be mistaken, the community is more trustworthy and that the goal of the sciences is closure which is attained when there is overwhelming consensus—consensus which is established through the fundamental mechanism of peer review. Moreover, that consensus is a consensus of experts (Collins, 2014; Crease and Selinger, 2006; Oreskes, 2019). Science is not a democracy where one scientist's views are as valuable as another. The views that matter are from those who have relevant background knowledge, skills in interpreting particular results, and awareness of potential flaws in reasoning. Thus, a petition claiming that vaccines are dangerous is meaningless if the signatories are not scientific experts on vaccination. Then there is a set of data literacy skills—the knowledge that correlations are not necessarily causal, knowledge of the common manipulations used to massage data to support an inappropriate interpretation, and of reasoning based on flawed samples. Finally, there is a need to develop the generic skills that are applicable in all disciplines advocated by those who are concerned about civic reasoning (Hertwig, 2017; Lee et al., 2021; Wineburg and McGrew, 2017).

In short, there is a need to take an externalist view of the sciences and ask what are the capabilities and knowledge necessary to become a competent outsider—somebody who knows that they stand at an epistemic distance to science itself but yet is capable of interrogating the work of scientists in a valid and justified manner (Feinstein, 2011). What Feinstein argued is that the focus of

traditional science on the canon of concepts and theories leaves them as “marginal insiders”—that is people with a repertoire of poorly understood ideas that are of limited utility. As he points out, a knowledge of fluid dynamics is hardly helpful when it comes to fixing your brakes. Rather, competent outsiders are “people who have learned to recognize the moments when scientific knowledge has some bearing on their needs and interests and to interact with sources of scientific expertise in ways that help them achieve their own goals” (Feinstein, 2011). Moreover, competent outsiders have had an education which has developed the basic tools required to interrogate expertise. The failure of school science to present something which is seen as useful to their lives simply leaves the student with the impression that they are sitting on a train with blacked out windows. They know they are going somewhere but only the train driver knows where and too many decide that the journey is not worthwhile and the effort too much.

Conclusion

So, if the sciences are hard, what do we know about how learning in the sciences can be supported? As previously indicated, it is important to understand that learning has to begin with what the students already know, or do not know. Eliciting this information is the beginning of a conversation. However, beyond this, while good quality explanation is significant, learning science must be seen as learning a new language. As Postman and Weingartner (1971) argue:

Almost all of what we customarily call “knowledge” is language, which means that the *key to understanding a subject is to understand its language* [emphasis added]. A discipline is a way of knowing, and whatever is known is inseparable from the symbols (mostly words) in which the knowing is codified. What is biology (for example) other than words? If all the words that biologists use were subtracted from the language, there would be no biology This means, of course, that every teacher is a language teacher: teachers, quite literally, have little else to teach, but a way of talking and therefore seeing the world (p. 102).

Thus, a more productive approach to learning science is to recognize what language teachers understand—that language is acquired by interaction and participation in the disciplinary practices that require the use of that language. In the case of science these are asking and framing questions, designing and evaluating experimental designs, analyzing and interpreting data, engaging in argument from evidence, and communicating and obtaining scientific information. Not for nothing did Chi find, in her extensive review of the evidence on learning, that there was a hierarchy to the efficacy of learning activities. The least effective are those where the recipient is passive and does little or no processing of information—copying notes being the archetypal example. “A device”, as one wit pointed out, “by which the notes of the lecturer become the notes of the student without going through the minds of either.” Then there are those activities which require the student to be active and cognitively process information, such as the demands made by a teacher question. Better are those which require the student to produce something—the solution to a problem, a written report or a Freyer model defining a concept such as “physical change” with examples and non-examples. Best, however, are those which require the student to be interactive, requiring the student to engage in dialog with another in the production of an artifact—be it a response to a clicker question, the production of a powerpoint presentation, turning to talk with a partner about a question posed by a teacher, or working collaboratively discussing what makes a good concept map (Chi, 2009). Hake’s evidence about the failure of direct instruction is unequivocal (Hake, 1998). In short, research of the past 50 years had clearly defined the nature of the challenge and the best ways of addressing it. Yet too many continue to do the same thing over and over again, expecting different results. As Einstein allegedly said—the definition of insanity.

Individuals read for many purposes. When individuals have questions, are attempting to solve problems, or seek to improve their understanding, they commonly access text. These purposes can be self-generated or assigned by others (e.g., teachers) and can be part of informal contexts (e.g., reading to understand the nutritional value of different foods) and formal contexts (e.g., reading as part of a class to complete an assessment task). For this article, we define *multiple texts* (or multiple textual sources) as different text-based sources about the same topic. *Learning from multiple texts* can involve selecting, comprehending, evaluating, and integrating information from two or more textual sources to carry out an assigned task or a self-selected reading goal (Braasch et al., 2018).

To illustrate, primary school students may be asked to read to determine whether a dolphin is a fish or a mammal. The students could be provided different texts about fish, mammals, and dolphins. They could identify the defining characteristics of fish and mammals, compare the characteristics of dolphins with the defining characteristics of fish and mammals, and subsequently infer that a dolphin is a mammal. Each text relates to a larger whole that is not specified by any single text. In this example, the teacher may provide students with texts that are deemed credible and provide information consistent with biologists' accepted understandings of fish and mammals. However, in other cases, readers may need to consider characteristics of the sources. An information source can be defined as the person or entity to whom the information is attributed (Macedo-Rouet et al., 2013). Suppose students are asked to evaluate the impact of progressive tax rates on different segments of the economy (e.g., job creation, capital investment, wage rates, foreign investment). This example differs from the previous example (dolphins) not only in the number and complexity of the concepts, but some of the texts may provide conflicting views. Thus, readers need to consider not only the content of a text, but also the source to whom the content is attributed.

The purpose of this article is to provide an overview of learning from multiple texts. The article consists of seven main sections. In the first section, we provide an overview of models that describe learning from multiple texts. In the second section, we review research on the role of individual differences in learning from multiple texts. In the third section, we describe how researchers measure readers' comprehension of multiple texts and their representation of information about sources. In the fourth section, we discuss approaches to teaching students to integrate content information across texts and to critically evaluate source information. In the fifth section, we discuss reading on the Internet (including social media) and the use of multimedia documents and sources. Finally, we end with general comments about learning from multiple texts.

Models of learning from multiple texts

Models are useful for trying to describe the processes and products of learning from multiple texts. Processes refer to the moment-by-moment activities that occur before, during, and after a reading experience. Products refer to the mental representations and external artifacts (e.g., notes, essays) that readers generate from a reading experience. In this section, we review seven models. The first model, the Construction-Integration model (Kintsch, 1988, 1998) was developed to describe how readers construct meaning from text, implicitly a single text. However, this model is foundational to subsequent models developed to describe learning from multiple texts. In particular, the Construction-Integration model introduces different levels of mental representation that inform subsequent models. These later models build upon and/or complement each other by specifying additional processes, variables, or contexts for describing how readers learn from multiple texts.

Construction-Integration (C-I) model

According to the Construction-Integration (C-I) model (Kintsch, 1988, 1998), two main processes facilitate comprehension. The first is *construction*, which begins when text information and prior knowledge are active in the reader's focus of attention. The text information can be the sentence currently being read or sentences read earlier. Sentences from the text can be fused with each other and with prior knowledge, forming a propositional network. The second is *integration*, which involves the continuous spread of activation throughout this network until activation settles on the overlapping nodes in the network, which decreases activation of isolated nodes or nodes that have less overlap.

Over the course of reading, the reader constructs a mental model of the text. The reader's mental model can be represented at three levels: surface code, textbase, and situation model (Kintsch, 1998). The *surface code* represents the exact wording and syntax of sentences. Readers typically only retain the surface code of the most recent clause. The *textbase* represents the gist meaning of the propositions stated explicitly in the text, rather than the exact wording and syntax. The *situation model* represents the reader's overall understanding of the information in the text. The situation model is the fusion of information in the text with the reader's prior knowledge. Thus, skilled readers generally create similar textbases, which reflect the content and organization as provided by the author. However, situation models may vary as a function of readers' goals, interests, and background knowledge.

Document models framework (DMF)

The C-I model (Kintsch, 1988, 1998) was conceived of as a framework for describing learning from a single text. Building upon the C-I model, Perfetti et al. (1999) introduced the Documents Model Framework (DMF) to describe the mental representations that are created when learning from multiple texts. According to the DMF, readers generate a documents model that includes a situations model and an intertext model. The *situations model* (or integrated mental model) reflects the individual situation model for each text, but also the inter-connections between/among the individual situation models. Thus, the situations model is a composite of the situation models for each text and represents the reader's overall understanding of the topic or phenomenon described in the texts. The *intertext model* contains information about the individual texts themselves and how they are related, such as each text's style (e.g., informational vs. narrative) and intent (e.g., to persuade or inform), the author's status, perceptions of text quality, and whether the authors of the different texts agree or disagree.

Multiple-document task-based relevance assessment and content extraction (MD-TRACE) model

The MD-TRACE model describes the resources and processes readers use when learning from multiple texts (Rouet and Britt, 2011). As with the Documents Model Framework, the reader generates a documents model (situations model/integrated mental model and intertext model) based on the texts. However, the MD-TRACE model extends learning from multiple texts to include a task model. A *task model* is the reader's understanding of the task requirements, which contributes to goal formation and suggests the means necessary to achieve that goal. Thus, when reading multiple texts, the reader not only constructs a documents model (situations model and intertext model), but also generates a task model that directs the reading activity.

The MD-TRACE model includes five core processes that occur *iteratively* over the course of learning from multiple texts. For simplicity, we will describe the processes as steps, but it is important to recognize that the process is iterative. The first step involves constructing a task model. It includes the goals readers create and actions that should be taken to reach the goals. The second step involves assessing information needs. These needs are clarity about the task to be done (e.g., write an essay vs. prepare for a multiple-choice test), familiarity with the task (e.g., knowing how to write an argument essay), prior knowledge about the content of the text, and what resources are needed (e.g., books, journal articles) and where to find them. The third step involves selecting, processing, and integrating document information. *Selection* involves determining the relevance of information in relation to the goal for reading. Information that more effectively contribute to a reader's goals is more relevant than information that less effectively contributes to a reader's goals (McCrudden and Schraw, 2007). Processing involves attempts to create meaning. It involves cognitive activities to make sense of ideas, connecting ideas from the text with each other, and connecting ideas from the text with prior knowledge. It can also include evaluations of the author/source as well as the texts themselves. The fourth step is the construction of a task product. The reader engages with multiple texts to reach some goal, which is generally reflected in the task model. The task product involves the utilization of the documents model and the external resources, such as the texts themselves, to create some

output. This can be simple, such as an oral response, or complex, such as a paper that synthesizes information from several sources. The last step involves assessing product quality. The reader assesses whether the product meets the task goals, and whether improvements are needed. All five of these steps draw heavily on readers' use of self-regulation.

Reading as problem solving (RESOLV) model

The MD-TRACE model (Rouet and Britt, 2011) highlights the decision-based nature of reading. The RESOLV model (REading as problem SOLVing; Britt et al., 2018; Rouet et al., 2017), extends this focus further. It includes three additional assumptions. First, dimensions of the reading context other than the task instructions influence reader goals. Second, readers' interpretations of contextual cues influence their goals. Third, motivation, interest, and value influence reading decisions, such as whether to read and what to read.

Readers generate goals for reading in context. As such, according to the RESOLV model readers generate a context model. A *context model* can include information about the request (what is the task statement), the requester (who is making the request), the audience (who will receive the completed request), supports or obstacles (what external resources are available and how can they support or impede request completion), and the self (the readers' assessment of their own skill, knowledge, and interest related to the request and their assessment of the perceived costs and benefits of the activity). Thus, readers who receive the same task instructions may generate different interpretations of the task context and/or have different levels of motivation for initiating, sustaining, and completing activities needed to achieve the task.

In both the MD-TRACE and RESOLV models, the reader creates a task model. In both, the task model includes the goal (goal state for the final product, subgoals, constraints) and how to accomplish it (plans, strategies). However, the RESOLV model also includes the values associated with subgoals (importance of desired states and methods). In other words, readers assess the value of engaging in effortful behaviors and strategies when deciding what to do while reading. Thus, the task model complements the context model.

Like previous models, RESOLV assumes that the mental product of a reading activity is a documents model (situations model/integrated mental model and intertext model). Rouet et al. (2017) further specify the nature of the intertext model. The *intertext model* represents source information (e.g., who wrote the document and in what context) and connections between content and sources. Source-to-content connections are links between a source and specific information or ideas from a particular document (e.g., who said what). Source-to-source connections are links between sources that represent readers' interpretations about whether information and ideas from different documents corroborate or conflict with each other.

Discrepancy-induced source comprehension (D-ISC) model

The discrepancy-induced source comprehension (D-ISC) model, which stems from the DMF, describes the cognitive processes readers use when reading to understand controversial messages (Braasch et al., 2012; Braasch and Bråten, 2017; Braasch and Kessler, 2021). The DMF is relevant to situations in which information from multiple sources is consistent, complementary, or conflicting. The D-ISC model is particularly relevant to situations in which multiple sources present conflicting information about the same issue (e.g., sun exposure is harmful vs. healthy). In these situations, readers need to understand the conflict and attempt to reconcile the different perspectives so they can build an integrated model of the situation or issue. One way to do this is to shift attention strategically toward the sources of conflicting information in order to resolve the conflict in light of the sources (e.g., by acknowledging that different authors may have different expertise or motives).

Content-source integration (CSI) model

The Content-Source Integration (CSI) model (Stadtler and Bromme, 2014) also describes how readers may use a document's source to draw conclusions about conflicting information. The CSI model consists of three stages. The first stage is *conflict detection*, which occurs when a reader perceives a contradiction between information from different sources. In this stage, readers notice when information they are currently reading conflict with information they have read previously. This introduces a coherence break. To restore coherence, readers engage in the second step, which is *conflict regulation*. There are three common ways that readers can restore coherence: (a) ignore the conflict (decide not to attempt to do anything to interpret the conflict) (b) reconcile the conflict using text (e.g., the text provides a satisfactory explanation for the conflict), or prior knowledge (e.g., use prior knowledge to explain the conflict), or (c) accept the conflict as due to different sources or points of view (i.e., interpret the disruption of coherence as due to different perspectives rather than a genuine conflict). The third stage is *conflict resolution*. In this stage, the reader needs to develop a personal stance on the conflict. They need to evaluate the truthfulness of conflicting claims, which entails making a first-hand or second-hand evaluation (Bromme and Goldman, 2014). When readers make first-hand evaluations, they use their understanding of the subject to assess the validity of the competing claims. The question to be addressed is: What is true? However, when readers have limited understanding of the subject, they may need to make a second-hand evaluation, which entails evaluating the sources themselves. The question then becomes: Whom to believe? Thus, when a topic is more familiar, readers may rely to a greater extent on first-hand evaluation, but when a topic is less familiar, readers may rely to a greater extent on second-hand evaluation (McCrudden et al., 2016).

Integrated framework of multiple texts (IF-MT)

The integrated framework of multiple texts (IF-MT; List and Alexander, 2019) describes the process of learning from multiple texts as a three-stage process. The first stage is *preparation*, in which the reader evaluates the reading task and develops a stance for how to complete it. Two dimensions characterize the reader's stance: affective engagement and behavioral dispositions toward the evaluation of sources and verification of information the sources provide (List and Alexander, 2017). *Affective engagement* refers to the degree to which students are motivated to complete a task. Motivational variables include topic interest, attitudes toward the topic, self-efficacy for the reading task, and value placed on doing the task. *Behavioral dispositions* refer to the extent to which readers have mastered the skills needed to evaluate sources and the content provided by sources, and their ability to integrate texts. Further, this dimension includes the extent to which the reader commonly uses these skills.

The second stage is *execution*, which describes the behaviors and strategies readers use while engaging with multiple texts. There are three core strategies. *Behavioral strategies* refer to the observable actions that readers take when they engage with the texts, including information search, text selection, and note taking activities. *Cognitive strategies* refer to the mental processes that readers use when they engage with the texts including strategies used to comprehend individual texts and strategies used to integrate ideas between/across texts. *Metacognitive strategies* refer to the regulatory actions that readers use when they engage with the texts, such as comprehension monitoring (i.e., self-evaluations of understanding).

The third stage is *production*, which involves the generation of an external product, such as an essay, to address the reading task. This usually reflects selective elements of the reader's mental representation of the texts, based on the specific task expectations. For instance, when writing a summary, the learner might include main ideas, but exclude some details that are retained in memory.

The role of individual differences

Working with multiple texts may result in a more complex and deeper understanding of a topic, issue, or phenomenon than working with one single text (Wolfe and Goldman, 2005). Further, working with multiple texts may lead to greater flexibility because the acquired knowledge is less tied to one specific text and therefore more accessible across different contexts (Spiro et al., 2015). However, there is no reason to believe that all learners will profit equally from working with multiple sources. Among the individual differences likely to play a role are learners' comprehension skills, prior knowledge, beliefs, motivation and engagement, and strategic processing.

Comprehension skills

Several recent studies have linked learners' single text comprehension skills to aspects of multiple text comprehension (e.g., Florit et al., 2019; Mahlow et al., 2020; Mason et al., 2020; Salmerón et al., 2020b). For example, Florit et al. (2019), in a study of Italian fourth-grade students, found that comprehension skills measured with a single informational text uniquely predicted multiple text comprehension measured with post-reading essay tasks. Likewise, Mahlow et al. (2020), in a study of German university students, found that comprehension skills measured with a single text predicted multiple text comprehension when controlling for other relevant variables. Such findings are consistent with the idea that comprehension of each single text indeed matters when learners try to build integrated understanding across multiple texts.

Prior knowledge

There is evidence that learners' prior knowledge about the topic discussed across multiple texts contributes to the comprehension of those texts (e.g., Bråten et al., 2014; Gil et al., 2010; Stang Lund et al., 2019). For example, Stang Lund et al. (2019) found that Norwegian upper-secondary students' prior knowledge both directly and indirectly predicted their ability to integrate source and content information when reading about the issue of sun exposure and health. Presumably, prior knowledge contributes to multiple source comprehension because it facilitates bridging inferences that create interconnection and coherence in complex, divergent textual materials (Bråten et al., 2020).

Results are mixed regarding the relationship between prior knowledge and attention to source information, such as the authors, when working with multiple texts. Notably, quite a few studies have found no relationship between prior knowledge and sourcing (for review, see Anmarkrud et al., 2021). This inconsistency seems to reflect theoretical divergence. For instance, some models (List and Alexander, 2017, 2019) imply that more prior knowledge will increase attention to source information through adoption of a critical analytic stance. However, others (Stadtler and Bromme, 2014) imply that less prior knowledge will increase attention to source information because learners do not feel competent in validating knowledge claims themselves.

Beliefs

Two kinds of beliefs have been studied in relation to multiple text comprehension. The first type of beliefs, called topic beliefs, concerns positions people take about the truth value of statements about some aspect of reality (Wolfe and Griffin, 2018). The second type, called epistemic beliefs, concerns positions people take about the truth value of statements about knowledge and knowing (Bråten and Strømsø, 2020).

Research has indicated that learners' prior topic beliefs may influence the comprehension of multiple texts, especially when those beliefs are inconsistent with information presented in the texts (for reviews, see Bråten and Strømsø, 2020; Richter and Maier, 2017). In such instances, learners tend to be biased toward their own prior beliefs when evaluating arguments and drawing conclusions, which does not bode well for creating a balanced mental representation of controversial issues discussed across multiple sources (Richter and Maier, 2017). However, learners may sometimes decouple their beliefs from the meaning making process and consider information independently of their prior beliefs, which increases the likelihood of belief revision and construction of a more balanced mental representation of the issue in question (McCrudden, 2020).

Much research has also been directed toward understanding the role of learners' beliefs about the nature of knowledge and the process of knowing when working with multiple texts (for reviews, see Bråten et al., 2016; Bråten and Strømsø, 2020). This research has indicated that believing that knowledge is tentative and complex and that the process of knowing involves justifying claims by corroborating and integrating information across sources may promote multiple text processing and comprehension (e.g., Barzilai and Eshet-Alkalai, 2015; Bråten et al., 2014; Wiley et al., 2020). Presumably, this is because such beliefs about knowledge and knowing are well aligned with the requirements of multiple text learning contexts, which involve open, complex problem spaces characterized by claims and arguments distributed across diverse, often conflicting textual sources (Bråten et al., 2020).

Motivation and engagement

Because comprehending multiple texts may be considered more challenging than comprehending a single text on a topic, it is reasonable to assume that comprehending multiple texts requires higher levels of learner motivation and engagement. Thus far, the motivation construct most researched in relation to multiple text comprehension is topic interest (e.g., Bråten et al., 2014; List, 2020; List et al., 2019b; Salmerón et al., 2018b; Stang Lund et al., 2019), although this research provides little support for a direct relationship between topic interest and multiple text comprehension. However, some research (Bråten et al., 2014; List, 2020) has suggested that topic interest may indirectly affect multiple text comprehension through behavioral engagement, that is, learners' active, observable involvement in tasks as typified by time, effort, persistence, and productivity (Eccles and Wang, 2012).

In a range of studies, behavioral engagement has been shown to be a proximal contributor to multiple source comprehension. In some of these studies (Bråten et al., 2018a; Bråten et al., 2014; Du and List, 2020; List, 2020; List et al., 2019b), the time learners invest in reading and comprehension tasks has uniquely predicted their comprehension performance. In other studies (Bråten et al., 2018a; Kammerer et al., 2021; Latini et al., 2019), learners' productivity (length of written responses) when working on post-reading essay tasks used to measure multiple text comprehension has been shown to be positively related to comprehension performance.

Strategic performance

At the same time, it is important to ensure that learners' engagement is channeled into adaptive strategic processing of the text materials. In particular, learners' use of cross-text elaboration strategies has been linked to multiple text comprehension (e.g., Bråten et al., 2014; Cho et al., 2017; List, 2020; List and Alexander, 2020; List et al., 2019a; McCrudden et al., 2021). These strategies involve intentional intertextual processing, such as connecting, comparing, and contrasting information across texts, to build an integrated understanding of the topic in question. Conversely, strategic processing that involves an accumulation of piecemeal information from single texts does not seem to promote integrated understanding of multiple texts (Bråten and Strømsø, 2011).

Strategic attention to source information, such as authors, publications, and date and purpose of creation, to evaluate information in light of its source, has been given special status within this area of research (Scharrer and Salmerón, 2016). Accordingly, a range of studies have indicated that learners' critical evaluation of source information is related to adaptive meaning making in multiple text contexts (e.g., Bråten et al., 2009; Cho et al., 2017; Florit et al., 2019; Salmerón et al., 2018a). Presumably, this is because it allows learners to prioritize information from competent, credible, and less biased sources, as well as to understand reasons for conflicting views on the same issue (e.g., because authors have different competencies or motives).

Measurement of multiple source comprehension

In reviewing the literature on multiple source comprehension, Primor and Katzir (2018) found that researchers had either used expressive tasks in the form of essays and open-ended questions or receptive tasks in the form of verification tasks to measure content integration across multiple texts. Essay tasks have sometimes been scored holistically (e.g., Anmarkrud et al., 2014; List et al., 2019b) and sometimes by segmenting them into idea units and identifying the types of inferences made (i.e., intratext vs. intertext inferences; Gil et al., 2010; Salmerón et al., 2018b). When open-ended questions have been used, they have directly or indirectly required learners to integrate different views across sources, capturing how well learners are able to reason about the issue in terms of the claims, reasons, and evidence provided across texts (Barzilai and Ka'adan, 2017; Bråten et al., 2014). In some instances (Le Bigot and Rouet, 2007; Latini et al., 2019), content integration has also been measured by taking learners' use of connective words into account. For example, Latini et al. (2019) scored undergraduates' written responses to open-ended questions by coding their use of causal (e.g., because, therefore) and adversative (e.g., however, whereas) connectives in combining, comparing, and contrasting information across sources.

Regarding verification tasks, Strømsø et al. (2008) introduced the intertextual inference verification task. This task requires learners to verify (yes or no) whether presented statements can be reasonably inferred by combining information across two or more texts recently read. Importantly, the statements included in an intertextual inference verification task should not just be combinations of statements included in the texts, but statements requiring the use of bridging inferences between information from those texts.

These different ways of measuring integration across multiple texts have different strengths and weaknesses. For example, whereas essays and open-ended questions seem well suited to assess deeper level, integrated understanding of multiple texts, such tasks involve additional writing skills. Ideally, writing skills should therefore be measured independently and their effects partialled out when researchers use essays and open-ended question tasks in correlational or experimental designs. Correspondingly, when learners respond orally instead of in writing to open-ended questions (e.g., Andresen et al., 2019), expressive oral language skills come into play and should preferably be accounted for. Whereas intertextual inference verification tasks do not require writing or expressive oral language skills, such tasks often have lower reliabilities unless they include a large number of items, and they involve a 50% chance of guessing correctly. Further, intertextual inference verification tasks typically include quite complex items (i.e., statements) that may be difficult to understand. As such, these tasks may require comprehension skills in and of themselves.

With respect to learners' representation of source information, an important distinction is between measurement of spontaneous (i.e., unprompted) and prompted representation of sources. For example, spontaneous representation of sources is measured through learners' references to source information or inclusion of source-content links when trying to explain conflicting positions on the same issue in an essay task, that is, without being given any specific instructions to refer to sources (e.g., Anmarkrud et al., 2014; Salmerón et al., 2018b). On the other hand, prompted representation of sources may be measured by probing learners' memory for source features after reading (e.g., Kammerer et al., 2016; Salmerón et al., 2018b), by asking them to rank or rate sources according to credibility (e.g., Barzilai et al., 2020b; Bråten et al., 2009), and by asking them to justify their ranking or rating of the sources (e.g., Braasch et al., 2014; Mason et al., 2018). As highlighted by Anmarkrud et al. (2021), learners generally have been found to perform rather poorly on measures of spontaneous source representation. On measures of prompted source representation, more variation among learners are typically found, which also makes it easier to discover relationships between learners' representation of source information and other variables, such as individual differences (Anmarkrud et al., 2021).

Noteworthy is also the development of scenario-based digital assessment tools within multiple source comprehension, such as the Online Research and Comprehension Assessment (ORCA; Leu et al., 2015) and the Global Integrated Scenario-based Assessment (GISA; Sabatini et al., 2018). In essence, scenario-based assessments involve purposeful reading of multiple thematically related sources, with built-in guidance provided throughout task completion and with both content integration and critical source evaluation targeted by the assessment (Sabatini et al., 2018). Wang et al. (2021) showed that a scenario-based assessment may be more difficult than a traditional single text comprehension assessment, with learners' prior topic knowledge also contributing more to performance on the former than on the latter. However, the scenario-based assessment that Wang et al. (2021) evaluated was based on only multiple-choice questions and did not seem to include guidance or assess critical evaluation of source information.

Teaching integration and sourcing skills in multiple text contexts

Given the great challenges that multiple text comprehension represents across educational levels, direct instruction and guidance seem necessary. This means that making multiple texts available to students, or even providing them with a selection of relevant sources, is hardly sufficient. In such situations, students may still perceive the task as one of gathering and reproducing as much information as possible from different texts, without constructing a coherent representation of the topic by integrating information across texts and without critically evaluating the credibility of the content in light of the source information. Students must therefore learn *how* diverse and complex text materials should be handled. In the following, we discuss approaches to teaching integration of content information across texts and critical evaluation of source information, respectively.

Teaching content integration

In a review of interventions targeting integration of information across multiple texts, Barzilai et al. (2018) showed that many of these interventions have emphasized collaboration and discussion among students. In such interventions, students have typically worked in pairs or small groups in which they have discussed texts and engaged in various text-based writing activities. As an example, Lundstrom et al. (2015) had students work with multiple texts individually before they shared what they had learned with their group. Students then organized information from the texts collaboratively and created an outline for writing a synthesis based on the texts.

Other interventions targeting content integration have emphasized various forms of strategy instruction, that is, guidance in using strategies to integrate content across texts (Barzilai et al., 2018). These interventions include guidance in how to annotate or summarize single texts (e.g., Britt and Sommer, 2004; Hagerman, 2017), as well as guidance in how to create and use graphic representations (e.g., tables or maps) that explicate how information from different texts hang together (e.g., Barzilai and Ka'adan, 2017).

In an 8 h intervention where Israeli ninth-graders worked with multiple texts on a historical topic that included both complementary and contradictory information, Barzilai et al. (2020a) combined student discussions and graphic representations. Students

learned to represent relationships between the contents of multiple texts graphically by means of a map, in which they also mapped connections between content and source information and between sources of information. Students used this graphic representation when they produced their own texts on the topic. They worked in pairs both when they mapped the connections between the texts and when they produced their own texts, and they also discussed their experiences with writing with support from the map in class. The results of this intervention showed that students who created and used the graphic representation collaboratively clearly outperformed students in a control group with respect to integrating information across texts on an essay task.

Teaching source evaluation

A number of interventions targeting sourcing skills have been implemented and evaluated during the last decades (for review, see Brante and Strømso, 2018). However, many of these interventions have been quite brief, implemented by researchers rather than teachers, and failed to provide evidence for long-term effects (Brante and Strømso, 2018).

As an example of an extensive intervention implemented by teachers as part of regular classroom activities and demonstrating not only immediate but also long-term effects, Bråten et al. (2019) conducted a study in which high school students were taught to consider relevant source features (i.e., author, author competence, author affiliation, type of document, publisher, publication date) when selecting texts, interpreting and evaluating content information, and writing from multiple texts. This six-week intervention was integrated into regular classroom activities in language arts and implemented by regular teachers who participated in professional development seminars led by the research team. The intervention built on a contrasting cases approach (Schwartz and Bransford, 1998) in which students were presented with two fictitious students who varied with respect to source evaluation skills, and they were tasked to compare and contrast these students' strategic attention to source information when working on authentic multiple text tasks framed by the curriculum. In this way, students were presented with a model of how they could approach multiple text tasks effectively, that is, by trying to emulate the sourcing skills illustrated by the "adaptive sourcer" case.

Results showed that students who participated in the intervention put more emphasis on source information when selecting texts, processed the selected texts more thoroughly, and more frequently attributed textual ideas to their respective sources during text-based writing than did students in the control group. Importantly, these effects were observed on far transfer tasks and were maintained over a 5.5-week period (Bråten et al., 2019).

Another example of a successful approach to teaching source evaluation is an extensive Finnish intervention study in which sixth-graders were taught to evaluate the credibility of multiple Web pages (Hämäläinen et al., 2020). This intervention, which also was implemented by the students' regular teachers, shared some important features with the Bråten et al. (2019) study. Thus, the younger Finnish students also were presented with and asked to compare contrasting cases that varied with respect to source evaluation, discussed source evaluation with each other and with the teacher, and practiced source evaluation when working with authentic multiple text tasks integrated in subject matter teaching. The results of this intervention showed that students who had participated in the intervention, as compared with a control group, to a larger extent based their evaluation of the credibility of Web pages on relevant source features, such as author expertise. However, no follow-up data were provided in this study.

Further research directed toward the design, implementation, and evaluation of long-term, classroom-based interventions is highly needed in this area. Preferably, teachers and researchers should collaborate to conduct such intervention research. Further, it should take place within the framework of regular subject teaching, where the taught sourcing skills can be practiced while working with authentic tasks that involve the evaluation of students' academic performance. Finally, although the teaching of source evaluation and the teaching of content integration have been discussed in two separate sections, it seems essential that these aspects of multiple text comprehension, in line with theoretical accounts, are integrated in educational interventions. The effects of such interventions also need to be evaluated on different tasks and on delayed post-tests to investigate the transferability and sustainability of those effects.

Reading on the internet

Understanding how students read on the Internet requires an understanding of Internet sources. First, all Internet sources are linked to other sources by means of hyperlinks. Reading a printed book involves collecting a book from a library or book store, whereas reading from the Internet often involves inspecting a search engine results page (SERP) to click and access a particular web page. Accordingly, reading on the Internet demands specific navigation competences, or the ability to select texts to read and the sequence in which to read those texts (Cho and Afflerbach, 2017).

Second, the Internet was created with an open editorial philosophy, which means that anybody with Internet access can share content with the rest of the World. The quality of printed books is often maintained by editorial gatekeepers (editors, librarians), whereas content on the Internet is not subject to the same editorial standards and can range from high-quality content written by authors with content-area expertise to low-quality content provided by novice or biased sources, such as bots spreading fake news (Braasch and Graesser, 2019). In a survey conducted in 2018, approximately two-thirds of EU citizens reported that they encountered fake news at least once a week (European Commission, 2018). Accordingly, reading on the Internet requires that readers regularly use active sourcing processes to filter, select, and interpret multiple texts (Bråten et al., 2020).

Third, the open nature of the Internet enables easy access to vast amounts of texts on virtually any topic. Thus, Internet readers have easy access to complementary information, alternative (or opposing) perspectives, or information in different formats (e.g., text, animated pictures, videos). But as Internet sources are created as single entities, and not as part of a coherent document, chances are high that documents referring to the same topic are not easily comparable. For example, they may lack contextual information, use different terminology, or use different types of arguments (e.g., scientific claims vs. personal accounts). Thus, reading multiple texts via the Internet may require continuous effort to integrate multiple sources across different formats.

Empirical evidence for the existence of the three major competencies that can be assumed to constitute the core of Internet reading (i.e., navigation, evaluation and integration), comes from a study by Kiili et al. (2018), who modeled the factor structure of scores on an Internet reading assessment in a large sample of sixth grade students (ages 12 and 13). They identified six factors that could be further categorized within the three major competencies: Navigation (1 factor: locating information with a search engine), Evaluation (3 factors: questioning credibility of information, confirming credibility of information, and communicating a justified, source-based position), and Integration (2 factors: identifying main ideas from a single online source, and synthesizing information across multiple online sources). Yet, empirical studies consistently show that young adolescents frequently display limited Internet reading competencies. For example, young readers frequently struggle to navigate, evaluate, and integrate digital information (e.g., Keil and Kominsky, 2013), and they often have difficulty evaluating the credibility of the sources they encounter (e.g., on YouTube or Twitter; e.g., Breakstone et al., 2019). Because such difficulties create particular challenges for younger or less-skilled readers, it is important to understand how Internet reading competences develop during school. Although some cross-sectional studies have investigated how navigation and evaluation competencies develop during school (Breakstone et al., 2019; Keil and Kominsky, 2013; Potocki et al., 2020; Rouet et al., 2011; Salmerón et al., 2018a), less is known about how the ability to integrate Internet sources develops. A widely used indicator of navigation efficiency is the percentage of relevant pages visited (e.g., OECD, 2009). This index takes into consideration that some Internet pages include relevant information for completing learning tasks, whereas other pages include irrelevant or distracting information. Navigation is positively related to students' reading comprehension abilities (Salmerón et al., 2018a). The challenge is that readers must use a few words in a hyperlink to infer the extent to which it contains semantically relevant information.

Like reading comprehension, navigation competencies increase with grade level across adolescence. Salmerón et al. (2018a) analyzed navigation (log-files) from a sample of adolescents that completed a digital reading assessment constructed on the basis of the PISA framework (OECD, 2009). Results revealed that navigation efficiency tended to be rather high, with average percentages of navigation efficiency between 80 and 85%, meaning that for every 10 pages visited, 8–8.5 contained relevant information for the students' goal. In terms of development, seventh and eighth graders showed similar navigation efficiency, but were less efficient than ninth and 10th graders, who also showed comparable navigation efficiency. Such development resembles the pattern obtained by Keil and Kominsky (2013), who asked participants to rate the relevance of pages from a list of four pages, where only two were semantically relevant to the learning goal. Participants' ability to detect relevant links substantially improved between the 6–7th grade and 9–10th grade samples. Interestingly, scores did not improve beyond 10th grade (11–12th grade and undergraduates). In a similar study, Rouet et al. (2011) found that young adolescents (5th grade) were highly influenced by superficial cues, such as using uppercase keywords in the hyperlink, regardless of their topic relevance. The influence of superficial cues on navigation gradually decreased and eventually disappeared across 7–11th grade students.

The assessment of evaluation competence usually includes the ability to identify sources, interpret source expertise and intentions, and to use such knowledge to judge the quality of information (Bråten et al., 2018b). Potocki et al. (2020) used an inventory to investigate the development of evaluation competence in a sample of 5th, 7th, 9th-graders and undergraduates. Overall, students across all age groups were proficient at identifying source elements (e.g., author) when requested to do so. Regarding source interpretation, the ability to discriminate competent from less competent authors increased gradually across the grade levels assessed, but the ability to discriminate benevolent from biased sources was more challenging and did not progress across grades. Finally, the ability to justify the selection of pages from a SERP based on source characteristics was challenging for fifth graders, with less than 10% citing source features to justify their selections, but increased across grades (approx. 45% in seventh grade, and approx. 65% in undergraduates).

Breakstone et al. (2019) assessed evaluation competence, specifically the ability to use source features to judge the quality of information. A representative sample of US high school students from grades 9th to 12th were presented with a set of Internet documents (Facebook posts, social media posts, or webpages), and they were asked to judge their credibility (e.g., Evaluate whether a video posted on Facebook is good evidence of voter fraud). Responses were coded using a rubric with three levels: beginning (incorrect responses), emerging (in the right direction but without proper reasoning), and mastery (effective evaluation by investigating sources and evidence). Overall, task performance was rather low, with participants obtaining emerging or mastery levels ranging across different tasks from 1% (min) to 39% (max). Regarding the development of evaluation competence, a small but continuous progression was observed across high school grades. Nevertheless, even 12th grade students scored well below mastery performance.

In sum, Internet reading competencies should be explicitly taught and practiced throughout the high school years. Several programs have been implemented to improve students' navigation, evaluation, and integration of Internet documents (for reviews see Barzilai et al., 2018; Brante and Strømsø, 2018; Salmerón and Llorens, 2019). In general, such programs have successfully increased high school students' specific competences. Still, current instructional programs do not fully consider the interrelated nature of Internet reading competencies. The three competencies are closely related and, potentially, students' engagement in

any one of them may support or trigger the other two (Salmerón et al., 2018a). Recent research efforts have identified possible types of adaptive coordination between the competencies (e.g., Delgado et al., 2020; Kammerer et al., 2016; Salmerón et al., 2020a; Sampietro and Salmerón, 2021), and there is a clear need to move from instruction addressing each competence in isolation toward instruction teaching students to self-regulate their knowledge construction during Internet reading by coordinating the required competencies.

Conclusion

As the nature of reading contexts in the 21st century changes, models of learning from multiple texts will need to be developed to provide a basis for representing and understanding how readers create meaning. Several individual difference variables play a key role in understanding how readers learn from multiple texts. The variables include (but are not limited to) comprehension skills, prior knowledge, beliefs, motivation and engagement, and strategic processing. Measurement of reading processes and the products of reading play a key role in understanding how readers learn from multiple texts and how individual differences impact learning. Similarly, by understanding how readers learn from multiple texts, interventions and instruction can be developed to promote engagement and learning. Importantly, readers not only need to be able to locate, comprehend, evaluate, and integrate texts, they need to be able to critique sources to whom texts are attributed (sourcing). Readers in the 21st century are consumers of information in an age dominated by rapid access to vast amounts of information. Thus, the challenge moving forward is to consider how readers can complement their roles as consumers of information to builders of knowledge.

Introduction

There is broad consensus across the world that the essential purpose of learning an additional language (hereafter L2), at whatever level of the educational endeavor (primary, secondary, or tertiary), is for learners to be able to communicate with first language (L1) speakers in the target language (TL). In the late 1960s, this consensus began to give rise to the phenomenon that became known as Communicative Language Teaching (CLT), or the “communicative approach.” CLT represented an alternative to strongly grammar-focused or literature-oriented “academic” programs that had hitherto dominated L2 teaching and learning for many years (such as so-called grammar-translation). CLT is now well established worldwide as a leading paradigm for L2 pedagogy.

In the context of wider debates about human learning and development, CLT does not represent just one approach or method. Rather, it acts as an umbrella label for a range of approaches. These share in common the goal of enhancing learners’ communicative competence in the L2. However, over the years these approaches have developed different emphases and taken several contrasting directions. Summarizing significant issues reported in some detail in [East \(2021\)](#), the purpose of this article is to trace key aspects of the development of CLT, in theory and in practice, and thereby to provide a historical account of its emergence alongside contemporary implications. The article considers L2 learning in both naturalistic environments, or so-called *second* language contexts, where the TL and the language of the majority of the community may be the same (e.g., learning English as L2 in Australia), as well as so-called *foreign* language contexts where the TL is not the same as the language of the majority of the community (e.g., learning French as L2 in the UK). In both contexts, the focus is on what goes on to support language learning in classrooms (instructed L2 learning). The article also explores some of the tensions that have emerged as theorists, researchers, and pedagogues have sought to pinpoint optimal conditions for the learning of an L2 from a communicative perspective.

Contrasting theories of learning

A fundamental question for all those who have a stake in the contemporary L2 educational endeavor is “how do students best acquire an L2 for communicative purposes?” Attempts to answer this question have taken stakeholders in several directions as they have explored not only theories of second language acquisition (SLA) but also what has become known as the phenomenon of *instructed* SLA, or ISLA (see [Loewen, 2020](#), for a useful overview). [Mitchell et al. \(2019\)](#) argued that explorations of effective SLA sit within broader discussions about human learning in general. As they put it, “[h]ow much of human learning derives from innate predispositions, that is, some form of genetic pre-programming, and how much of it derives from social and cultural influences as we grow up?” (p. 11). The so-called *nature-nurture* debate that lies at the core of Mitchell et al.’s two questions has influenced (and continues to influence) pedagogical thinking and pedagogical practice in classrooms, both more generally and with specific reference to classroom-based L2 teaching and learning. Before considering the relevance of nature versus nurture for learning an L2 in the classroom, the next section explores how the debate has influenced our understanding of first language (L1) acquisition.

Theories of learning and L1 acquisition

The *nurture* side of the learning debate finds its starkest expression in the psychological theoretical standpoint referred to as behaviorism—a perspective on learning that has a very long history but was particularly pervasive in the US during the 1940s

and 1950s, and influenced, among others, by the work of the American psychologist Burrhus Frederic Skinner (1904–1990). Skinner proposed the theory of *operant conditioning*—the notion that behavior is determined by consequences: when a particular behavior is positively reinforced, it is likely to occur again; when it is punished, its re-occurrence is less likely.

When it comes to young children learning their L1, a typical behaviorist perspective would be that children come into the world as *blank slates* (*tabula rasa*) and all the knowledge they need to grow and develop can be written on those slates. From this standpoint, L1 acquisition occurs as a result of children imitating and practicing the sounds and language patterns they encounter in their environments. Successful instances of attempted communication (positive reinforcement) lead to habitual and ingrained patterns of language use that enable children to develop their L1 proficiency. Thus, from a behaviorist perspective, what is needed is for young children to be consistently exposed to, and imitate, accurate samples of language.

In the 1960s, the behaviorist stance on L1 acquisition was challenged by a contrasting theoretical perspective—innatism—which owed much to the work of Noam Chomsky (1928–date), an American theoretical linguist. Chomsky's theorizing began what Atkinson (2011) described as a “cognitive revolution” (p. 6) that represented not only “a direct response to American behaviorism” (p. 8), but also the *nature* side of the debate about L1 acquisition.

Critiquing Skinner's (1957) book on verbal behavior, Chomsky (1959) argued that behaviorism, as Lightbown and Spada (2013) explained it, “failed to account for ‘the logical problem of language acquisition’—the fact that children come to know more about the structure of their language than they could reasonably be expected to learn on the basis of the samples of language they hear” (p. 20).

That is, the language samples that children are exposed to in their environments are often incomplete, sometimes inaccurate, and do not represent all the permutations in which segments of language can be put together. Nevertheless, children do develop the skill to put isolated components of language together successfully and correctly—they can form complete chunks of language even if they have not necessarily encountered every linguistic permutation. Chomsky speculated on this basis that children's minds are *not* blank slates, and L1 acquisition cannot simply be explained by imitation, repetition, and positive reinforcement. Rather, in his view, the child's innate ability explained the acquisition—children can reason things out for themselves and construct correct patterns from individual pieces of language they have encountered.

Children, Chomsky theorized, have been biologically programmed to acquire language because they possess what he termed a Language Acquisition Device (LAD). Furthermore, they have been born with an innate ability to work out the rules of language for themselves because they can align the rules in some way to an internal template that contains the framework that governs all language systems—what Chomsky labeled Universal Grammar (UG). Thus, from an innatist perspective, the child's inborn capability is fundamental to L1 development.

Behaviorism and innatism represent two fundamentally different and radically oppositional stances on learning. Mitchell et al.'s (2019) “how much?” questions suggest, however, that effective learning is not necessarily down to an exclusive either-or; rather, it is a matter of degree. A third theoretical stance on human learning, which we could label *interactionist*, attempts to reconcile purely behaviorist or purely innatist standpoints.

An interactionist perspective on L1 acquisition considers the linguistic environment *in interaction with* the child's innate ability. It is built on the assumption that both components are necessary and suggests that language proficiency develops as a consequence of the complex interaction between the environments to which the child is exposed (home, school, etc.) and the child's unique human characteristics.

An interactionist stance on early learning in fact owes much to the theorizing of two influential psychologists of the very early 20th century—Jean Piaget (1896–1980) from Switzerland and Lev Vygotsky (1896–1934) from Russia. The work of these two illustrates somewhat different positions on the nature-nurture interface as far as L1 development is concerned: Piaget seemed to place greater emphasis on children's internal cognitive processing ability, and, for him, a crucial element was children's active role in the learning process through self-discovery (see, e.g., Piaget, 1926). Vygotsky seemed to be more concerned with the influence of the environment, and his sociocultural-interactionist theory of learning (see, e.g., Vygotsky, 1978) put learning down to a social process and collaborative interaction with more capable peers who would provide the child with *scaffolding* which supports the child's evolving L1 development.

Translating theories of learning to the L2 context

It might be reasonable to assume at this point that an interactionist perspective on learning is a more reasonable or logical proposition than a separatist either-or standpoint (and this proposition will be revisited later in this article). Nevertheless, and turning now to the historical development of classroom-based L2 learning approaches, a range of perceptions demonstrates that, in both theory and practice, the situation has not been clear-cut. The next section traces developments to the CLT paradigm, highlights their strengths and limitations, and draws conclusions about optimal learning conditions in the L2 classroom. This historical overview is designed to illustrate the theoretical drivers for the diverse ways in which CLT has been operationalized over the years.

Benson and Voller's (1997) succinct summarization of the emergence of CLT underscored its significance at the time. They noted:

From time to time, a new concept enters the field of language education as an alternative method or approach, but rapidly grows in significance to the point where it comes fundamentally to condition thinking throughout the field. Such was the case with Communicative Language Teaching ... which began life in the late 1960s as an alternative to "structural" and "grammar-translation" models of teaching, but rapidly became an axiom of language teaching methodology (p. 10).

Benson and Voller (1997) continued that, against a backdrop of increasing recognition that L2 learners needed to acquire skills in communicating with others across the globe, CLT turned its back on "traditional anglocentric assumptions" that the overriding purpose of learning an L2 was "to broaden the mind" (as realized, e.g., through the study of literature in the TL). Instead, CLT "focused attention on learners who were learning languages because they needed to *use* them in an ever-shrinking world" (p. 11). As East (2008) put it, CLT represented "a distinct move away from artificiality of language with its emphasis on frequently decontextualized grammatical structures and vocabulary learning." It represented, as an alternative, "a move towards an understanding that language exists for purposes of *real* communication with *real* individuals in *real* contexts" (p. 14). The genesis of the communicative movement was traceable to simultaneous developments in both Europe and the US (Savignon, 1991), thereby becoming informed by a broad range of views about the nature of both language and language learning. It soon became an *international* initiative due to its attempt to respond to the perceived needs of L2 learners in a range of contexts.

Quite apart from substantial increases in travel and migration for which language in use was becoming important, the 1960s represented a turbulent time in history for many other reasons. Societally, this period witnessed significant challenges to the status quo from several quarters (Christison and Murray, 2014). In the context of education, at least in the US, so-called "Romantic Radicalism" challenged and denigrated teacher-dominated approaches and experimented with child-centered schools and programs, and experiential learning (Glatthorn et al., 2018). Chomsky's ideas represented arguably the most radical counter-influence to behaviorist stances on learning to arise in the 1960s, at least with regard to acquiring a language. As CLT began to emerge, Chomsky's theorizing around language acquisition became influential in the critiquing of strongly teacher-led pedagogical models. However, as the CLT movement began to build in momentum during the 1970s, there were inevitably tensions as more traditionally-oriented teachers, who may or may not have wanted to step onto the CLT bandwagon, grappled with what CLT might look like in their thus far grammar-oriented classrooms. Thus, in light of all else that was happening at the time, CLT had the potential to become a radical phenomenon for language education, heralding sweeping changes to practice. The reality as CLT began to unfold was more subtle and more complex (see, e.g., Medgyes, 1986; Rose, 2019).

Part of the early process of attempts to build a level of cohesion for the communicative movement was the articulation of *communicative competence* as the underlying theoretical framework. One early influential model, based on CLT principles that were beginning to become apparent and accepted, was presented by the Canada-based researchers Canale and Swain at the start of the 1980s. Although their model has been developed by others (the introductory chapter in Walker et al., 2018, presents a useful historical overview), the model represents a concise formulation of what Canale and Swain (1980) described, at this formative time in CLT's history, as "the content and boundaries of communicative competence" which, they maintained, would lead to "more useful and effective second language teaching" (p. 1). There were four dimensions (Canale, 1983):

1. *Grammatical or formal competence*, or knowing the rules;
2. *Sociolinguistic competence*, or knowing the language that is appropriate for the context;
3. *Discourse competence*, or knowing how to engage with extensive use of L2 in context;
4. *Strategic competence*, or knowing what to do when you do not know something in the L2.

This useful theoretical framework was, however, differentially realized as CLT began to become more widely influential in classrooms.

A teacher-led model of CLT

By the 1960s, strongly behaviorist-influenced pedagogical approaches to classroom-based L2 learning had become the status quo (Richards, 2006). In these approaches, the teacher as expert and leader would impart knowledge and explain principles (e.g., how grammar works); the learners would sit passively and, as *tabula rasa*, soak up the imparted knowledge; they would then practice what they had been taught (e.g., through grammar exercises). Drilling, repeating, and memorizing would be key components, and feedback on language use would focus on accuracy, with a view to positive reinforcement (i.e., praising correct language use and correcting language errors so that patterns of correct language use could become habitual).

Theorizing the behaviorist-informed stance from the perspective of grammar learning, Long (e.g., 2000) described the approach in the top-down, teacher-led classroom as *focus on forms* (FonFS). FonFS, as the name suggests, pays specific attention to the forms or rules of the language. In the grammar-translation classroom, this would have been to the exclusion of any communicative language practice. The grammatical forms to be taught would be presented in a textbook or synthetic syllabus, and ordered in a hierarchy from simple to more complex. Decisions around sequencing were often made on intuitive or arbitrary rather than objectively

defensible grounds (i.e., teachers or textbook writers making assumptions about what is grammatically straightforward and what is less so). The rules would be presented one at a time and practiced through grammar drills, exercises, and translation, alongside memorization of chunks of language.

A form of CLT that emerged early in the development of the communicative paradigm became known as the “weak” model. Weak CLT essentially reflected many of the teacher-led principles that had informed earlier approaches. In essence, the ostensible focus was communicative, with learners being introduced to situations or contexts for communicative language use (e.g., what to say in a café/hotel/airport) and/or different functions for which the L2 might be required (e.g., asking for something, saying sorry, negotiating). Weak CLT tended to foreground memorization of the correct language for the circumstances; it also foregrounded grammar teaching (as in grammar-translation). This was often through the “classic lesson structure” of Presentation-Practice-Production or PPP (Klapper, 2003)—first, teachers *presented* the grammatical rule; second, learners *practiced* the grammatical rule through grammar exercises; third, learners *produced* the grammatical rule, often through some kind of structured role-play undertaken in pairs or groups (e.g., ordering food and drink in the café; checking into the hotel). The communicative activity was designed to practice the rule. Weak CLT thus favored accuracy over fluency. Although dimensions that were later to find their way into Canale and Swain’s articulation of communicative competence were ostensibly attended to (e.g., grammatical competence, sociolinguistic competence), the pedagogical approach was essentially top-down, teacher-led, and behaviorist-informed.

In Long’s (2000) words, lessons based on an FonFS model, which focused in a linear way on linguistic items which students were required to learn and use accurately, tended to be “rather dry” (p. 181) and to “produce boring lessons, with resulting declines in motivation, attention, and student enrollments” (p. 182). Crucially, from a communicative perspective, there was little, if any, opportunity to use language creatively or spontaneously beyond the confines of the practiced language, and the development of higher levels of communicative competence was thereby compromised.

A learner-centered model of CLT

Strong interest in an innatist-informed learner-centered and experiential approach to L2 learning was fueled by the theorizing of the American linguist Stephen Krashen (1941–date), who, beginning in the 1970s, essentially toyed with Chomsky’s theories concerning the LAD and UG, but translated these ideas from the L1 to the L2 context. Krashen (1981, 1982, 1985) proposed that acquiring an L2 for communicative purposes was an entirely separate process from learning the rules of the L2. Furthermore, he theorized that *only* acquired language can contribute to communicative competence, and what is learned cannot be turned into acquired language. Krashen also theorized that L2 learners acquired the L2 through input alone, or, more precisely, through *understanding* the language they were receiving and processing in the classroom (the input hypothesis). *Using* the acquired language was a subsequent step.

Following Krashen’s theorizing, direct instruction about the L2 would be seen as unnecessary. Rather than sitting passively in class, learners would need to play a central role in acquiring the L2. Acquisition would be dependent on learners’ ability to think through and construct for themselves the rules underpinning the input. Fundamental here would be a great deal of contact with (or immersion in) the L2. All that would be necessary for L2 acquisition to occur would be exposure to input and opportunities for L2 learners to notice the rules for themselves.

Krashen’s ideas were foundational to the development of the Natural Approach (Krashen and Terrell, 1983; Terrell, 1977, 1982), so-called because it assumed that acquisition of an L2 followed the “natural acquisition processes” (as theorized by Chomsky) that were required to acquire the L1 (Terrell, 1982, p. 122). Within the Natural Approach, actually *using* the language communicatively was important. However, language use was not forced; rather, room was given for language use to emerge spontaneously after learners had had ample opportunities to process comprehensible language input.

Long (2000) described an innatist-informed approach to grammar in the bottom-up, student-centered classroom as focus on meaning (FonM). For Long, FonM, in stark contrast to FonFS, represented “a radical pendulum swing” (p. 182), and a stance taken by those who perceived significant limitations in FonFS, at least as far as communicative competence was concerned. The notion assumed (as Krashen did) that learners could decipher the grammar for themselves, just by being exposed to sufficient input in the TL.

So-called “strong” CLT emerged as a fiercely learner-centered reaction against teacher-dominant approaches, which were perceived as inadequate due to their emphases on repetition and memorization, grammatical accuracy, and controlled and limited samples of language. In its strongest form, emphasis would be placed exclusively on communication and group work. There would be no overt attention to the grammatical rules, based on the principle of immersion in the L2. Learners would be exposed to a range of authentic language input, with huge reliance placed on learners’ own cognitive processing ability. Consequently, strong CLT could be described as wholly experiential, and favoring fluency over accuracy. Although broader dimensions of Canale and Swain’s articulation of communicative competence were supposedly being addressed, the development of grammatical competence was largely considered to be implicit—a stance that, at its worst, could be construed as an “‘anything-goes-as-long-as-you-get-the-message-across’ approach to second language teaching” (Savignon, 1983, p. 1).

Long (2000) commented that FonM lessons are “purely communicative,” and conceded that they are “often interesting, relevant, and relatively successful” (p. 183). Furthermore, it may be argued that an FonM approach may lend itself better to second language contexts where opportunities are available to use the TL outside the classroom. However, Long went on to cite Swain (1991), whose investigations into the impact of learning French in the immersion context of bilingual Canada revealed that, even after 12 years of language immersion in the classroom, students’ command of grammatical principles remained sub-optimal—presumably because

they had simply failed to notice the correct forms in the input for themselves. Also, in classroom contexts where the L2 being taught is not the same as the L1 shared by many in the general population (i.e., *foreign* language contexts), there is arguably simply not enough time to expose learners to sufficient input, to “immerse” them in the language.

In summary, behaviorism and innatism (or nurture versus nature), as realized, for example, in the weakest or strongest forms of CLT, represented “two very contrasting approaches that inform teaching and learning—with the behaviourist approach being top-down, teacher-led and expository (teach students everything they need to know) and the innatist approach being bottom-up, learner-centred and experiential (let students work it all out for themselves)” (East, 2021, p. 8). However, it seems that both approaches are limited when it comes to determining the optimal conditions for classroom-based L2 learning from a communicative perspective to occur. Long (2015b) captured the essence of the problem, stating the “two major traditional language teaching orthodoxies” represented by CLT in its weakest and strongest forms were “excessively interventionist, on the one hand, and irresponsibly, wholly non-interventionist, on the other” (p. 20).

The emergence of more balanced CLT models

Earlier in this article, the suggestion was put forward that interactionism provides a more balanced and inclusive perspective on the components that are necessary for effective learning than the either-or proposals represented in behaviorism or innatism. Furthermore, interactionist perspectives as theorized, for example, by Piaget and Vygotsky, although somewhat different in emphasis, have contributed to the emergence of *constructivism* as a dominant paradigm for education in instructed contexts.

Constructivism emphasizes learners’ *active construction* of their own knowledge, in contrast to passively receiving information from teachers or textbooks. From this standpoint, primarily instructing learners (as in the weak CLT classroom) is not sufficient. Learners require opportunities to construct their own meanings, whether individually or working with others, and “raise their own questions, generate their own hypotheses and models as possibilities and test them for validity” (Fosnet, 1996, p. 29). Nonetheless, in the constructivist classroom, teachers have facilitative and supportive roles to play. From this standpoint, simply letting students get on with it (as in the strong CLT classroom) is also not sufficient. As Weimer (2013) noted, constructivist-oriented teachers do impart knowledge directly to students. The difference, however, is that usually “this direct transfer of information occurs *after* students have grappled with the issue, *after* they have a sense of what it is they need to know” (p. 23, my emphasis). The purpose of holding back from an initial period of instruction is that “once students realize they need to know something, they listen attentively for the answers” (p. 23).

How, then, has an interactionist/constructivist perspective on learning influenced CLT? This article has already presented the early and innatist-influenced ideas of Krashen. As non-interventionist ideas became subject to critique, developments to Krashen’s input hypothesis began to emerge that increasingly saw crucial roles for interactions between learners and interventions by teachers. Swain’s output hypothesis (Swain, 1985, 1995, 2005) was a developed notion that represented “an eloquent assault upon the input hypothesis” (Nunan, 2004, p. 80). Swain argued that learners of an L2 required opportunities to *produce* language through speaking or writing—that is, create output. When L2 users try to communicate something, they often come across barriers—items of language that they do not understand or do not know. When they become aware that they do not know something, they may amend what they are trying to communicate to get their message across more effectively and make it more understandable. In this sense, they “modify output.” Furthermore, when L2 users are *pushed* to create more accurate output, they may receive feedback on that output which helps them to notice what they do not know and take steps to overcome the gap. This process, according to Swain, helps learners to acquire more language and enhance the accuracy of their language because, as a consequence of feedback, they learn something new about how the L2 works. Implicit in Swain’s conceptualization was interaction—the means through which feedback and instruction could be offered.

Long took the matter further in his proposal of the interaction hypothesis (Long, 1981, 1983a,b, 1985, 1996). Long’s work in this space was so crucial that he has justifiably been described as “one of the founders of the modern Cognitive-Interactionist Tradition” (Markee, 2015, p. 23). Long argued that conversational interaction was an essential, or even sufficient, condition of L2 acquisition. The cognitive-interactionist perspective was built on the argument that communicative competence was essentially developed through face-to-face communication, and that learners learn how to communicate more effectively in the L2 as they seek to make their meaning clear to others (i.e., they do not just *modify* output—which might suggest a monologic activity; they *negotiate meaning*—implying at least two interlocutors). In this process, Long (1996) saw the need for corrective feedback that might be given by a teacher or more capable peer. This feedback would enable L2 users to undertake output modifications that would help them to negotiate meaning more successfully.

Long (2000) also theorized how grammar might be attended to from a cognitive-interactionist perspective, putting forward the notion of *focus on form* (FonF). FonF provides the space for teachers (or peers) to draw L2 learners’ attention to aspects of language, for example, language they are using incorrectly in their attempts to communicate. Crucial for Long, however, was that the attention paid to form must be in the context of L2 learners’ attempts to use language communicatively. That is, the grammar is not pre-selected, ordered, and taught in advance (as in FonFS); nor are learners left entirely to their own devices to work out the rules (as in FonM). Rather, teachers and learners both have roles to play in the co-construction of knowledge—in this case, the grammatical knowledge required for successful communication to take place. The aim is to induce noticing (Schmidt, 1990, 1993, 2001). The rules, whether noticed directly by the learner or indirectly through teacher or peer instruction/feedback, become available for acquisition. That is, “what learners notice in input is what becomes intake for learning” (Schmidt, 1995, p. 20).

An interactionist perspective on classroom-based L2 learning has also been influenced by the sociocultural-interactionist stance proposed by Vygotsky. From Vygotsky's socially-oriented perspective, learners must be enabled to work within their individual Zone of Proximal Development (ZPD), where the ZPD represents the space in which learners can move from what they initially cannot do on their own to what they can do independently as they collaborate with other, more capable peers and are scaffolded by them.

Thus, both cognitive-interactionist and sociocultural-interactionist perspectives place emphasis on meaningful interactions between L2 learners. In both cases, group work between learners would be a dominant feature of practice, but there would also be room for teachers (or peers) to intervene with instruction, explanations, or feedback. In other words, a constructivist approach to L2 teaching and learning is anticipated.

As communicatively-oriented theorists and practitioners began to wrestle with the crucial significance of *interaction* for purposes of SLA, the importance of interaction in the L2 became increasingly embraced in classrooms. Brown (2014), for example, spoke of a "turn-of-the-century wave of interest," influenced by a social-constructivist viewpoint, that saw increasing emphasis on three dimensions: language came to be viewed as "interactive communication among individuals, each with a sociocultural identity;" teachers were seen as "treating the language classroom as a locus of meaningful, authentic exchanges among users of language;" and L2 learning was perceived as "the creation of meaning through interpersonal negotiation among learners" (p. 206). In some instances, this has seen the rather limited "communicative" activities of the weak CLT classroom (e.g., role-playing buying food and drink in a café) develop into more open activities that allow greater room for creative language use.

One form of CLT to emerge around the early 1980s that has been heavily influenced by both cognitive-interactionist and sociocultural-interactionist perspectives is referred to as task-based language teaching or TBLT (see, e.g., Ellis et al., 2019). Essentially, TBLT sees "important roles for holism, experiential learning, and learner-centered pedagogy" alongside "the interactive roles of the social and linguistic environment in providing learning opportunities, and scaffolding learners into them" (Norris et al., 2009, p. 15). The construct of "task" represents "the hundred and one things that people *do* in everyday life at work, at play, and in between" (Long, 1985, p. 89) or "the real-world activities people think of when planning, conducting, or recalling their day" (Long, 2015a, p. 6). In TBLT, tasks are fundamental to interactive classroom activities and create greater freedom for learners to experiment with real language than the more structured role plays of the weak CLT classroom. Additionally, *task-based* suggests that these communicative tasks play a central role. Consequently, FonF has become a strongly advocated model for attention to the more formal aspects of language within TBLT.

It must be acknowledged that, over the years, TBLT has grown and developed in different directions that have emphasized elements of either weaker or stronger forms of CLT; it is beyond the scope of this article to explore these developments but see East (2021) for a more detailed discussion.

Drawing conclusions for optimal learning in the classroom

The above historical presentation of the CLT paradigm may have left some readers with the impression that developments to the paradigm have followed a logical and linear progression from a strongly behaviorist-informed teacher-dominant model (weak CLT) to a radically different innatist-influenced learner-centered and experiential model (strong CLT), and settling on a balanced model that fits within a constructivist view of learning and that consequently sees important roles for both teachers and learners in the L2 learning endeavor. However, the purpose of presenting the historical developments has in fact been to reach the conclusions that different historical emphases are still influential, and that there is value in considering dimensions of each of the stances on learning that have been outlined. As Van den Branden et al. (2009) observed, the pedagogical reality in many L2 classrooms is that teachers operate within "gradations of pedagogical choice," rather than within "two mutually exclusive extremes" (p. 3). These gradations of choice have been influenced as teachers have wrestled with messages about, and interpretations and applications of, sometimes very conflicting theoretical standpoints. The gradations are also influenced by the *context* for instructed L2 learning—where the TL and the language of the majority of the community may be the same (second language), or where the TL is not the same as the language of the majority of the community (foreign language).

Looking at educational approaches more generally, constructivism has secured a strong place as a theory of learning supported by research evidence that offers "a convincing commendation of learner-centered approaches" (Weimer, 2013, p. 54). It has nonetheless not been beyond critique. Coe et al. (2014), for example, asserted a counterclaim that "research evidence ... broadly favours direct instruction" (p. 23). Furthermore, it seems that behaviorist-informed principles continue to find a place in discussions about effective teaching and learning (see, e.g., Fischer and Hänze, 2019). These broader tensions in education are also reflected in the literature on effective approaches to L2 pedagogy. Adamson (2004), for example, argued that language *teaching* is "a complex undertaking," precisely because it is "shaped by views of the nature of language, of teaching and learning a language specifically, and of teaching and learning in general" (p. 604). Mitchell et al. (2019) maintained that L2 *learning* is "an immensely complex phenomenon" (p. 2), precisely because it is "coloured by debates on fundamental issues in human learning more generally" (p. 11).

It must also be acknowledged that the weak CLT model that was forcefully critiqued by those who advocated for learner-centered, experiential practices in light of the Chomskyan revolution of the 1960s in fact became, by the 1980s, "more or less standard practice" (Howatt, 1984, p. 279). By contrast, strong CLT did not really make huge inroads (see, e.g., Medgyes, 1986). Notwithstanding the emergence of TBLT as one means to address this imbalance, behaviorist-informed principles do continue

to be used in L2 classrooms. The direct teaching of grammar, alongside formal practice of grammatical rules, remains commonplace in many contexts (Larsen-Freeman, 2015). So too do vocabulary learning, repetition of phrases and sentences, pronunciation drilling, and memorized dialogues. These elements of L2 pedagogy cannot necessarily be dismissed as outmoded, irrelevant, or ineffective. Nonetheless, they must be viewed as part of a broader package.

Richards (2006) provided several perspectives on CLT that still hold true today. Although acknowledging that CLT finds its locus in “the notion of communicative competence as the goal of second and foreign language teaching,” Richards spoke of the wide and varied implementation of CLT approaches in attempting to reach that goal. Furthermore, as Richards made clear, CLT is influenced by a range of different educational paradigms and traditions. This means in practice that “there is no single or agreed upon set of practices that characterize current communicative language teaching.” Rather, CLT “refers to a set of generally agreed upon principles that can be applied in different ways, depending on the teaching context, the age of the learners, their level, their learning goals, and so on” (p. 22). This eclecticism in practice is reflected more recently in Mitchell et al.’s (2019) assertion that there can be “no ‘one best method’, however much research evidence supports it, which applies at all times and in all situations, with every type of learner” (p. 406). Indeed, and as acknowledged at the start of this article, CLT represents a broadly-based *approach*, rather than a specific *method*. In fact, in an era that some have described as “post-methods,” principled eclecticism which incorporates selecting methods deemed to be appropriate to the teaching and learning context is encouraged (Richards and Rodgers, 2014).

Putting a communicative approach into practice

Taking all of the above into account, which principles might help guide teachers to create optimal conditions for learning in instructed L2 contexts, whether second or foreign language?

Fundamentally, and drawing on the different theoretical perspectives presented above, one thing is clear: if L2 learners are to develop their communicative competence, there needs to be plenty of exposure to authentic TL input, and plentiful opportunities for students to interact with others, in the TL, around that input. It is in this respect that the L2 context arguably makes a difference.

In second language contexts, opportunities for L2 learners to interact authentically with TL speakers beyond the classroom are plentiful (in theory at least), and learners can be immersed genuinely in language and can try things out for themselves. In practice, although outside-of-class opportunities may be there, learners, for a variety of reasons, may not necessarily take full advantage of these. However, interactions in the classroom can build on the context, perhaps even linking classroom-based work with specific outside-of-class language use goals so as to help learners to take full advantage of authentic communicative opportunities (e.g., learners might be supported to undertake, whether as individuals, pairs, or groups, specific outside-of-class projects that require negotiating meaning with L1 speakers). In foreign language contexts, by contrast, there may be minimal or no opportunities for L2 learners to interact authentically with TL speakers beyond the classroom. In these cases, emphasis will need to be placed on creating ample opportunities for peer-to-peer interactions in the classroom. In both contexts, interactional opportunities present means through which learners can develop (among other things) their sociolinguistic, discourse, and strategic competence.

Attention to form (i.e., the development of grammatical competence) has also been established as an important component of L2 learning. Following on from ample opportunities to use the TL communicatively, the L2 context will also make a difference when it comes to the attention paid to the rules of language. In second language classrooms, there may be less necessity for TL interactions to dominate, and grammar instruction and practice may become more of a focus. In foreign language classrooms, grammar instruction, although important, may need to become more peripheral so as not to detract from interactional opportunities. In both contexts, however, where an important emphasis of classroom activity is on interactions between pairs and groups, teachers have crucial roles to play with regard to grammar. That is, instruction in, and feedback on, language in use are important components of L2 learning, whatever the context. The purpose of instruction and feedback is to enable learners to move from one level of competence to a higher level of competence in using the L2. The question becomes how to cater for direct instruction and corrective feedback in ways that support opportunities for learners to communicate authentically but that also help learners to learn how to handle language better (i.e., more accurately).

There would appear to be no advantage in dealing with grammar abstractly as a specific phenomenon of study (as in FonFS). That is not to say, however, that there is no place for the direct teaching of grammar rules or discrete practice of the rules. It is to say that grammar should be approached in the context of its contribution to effective (or accurate) communication.

A *communicatively*-oriented approach to grammar may well arise from what learners notice about language as they engage with TL input and/or interact with others in communicative contexts (FonF). In this sense, the focus on grammar is integrated into communicative language use. This approach might include both feedback on language use, either during or after the interactive activity, and direct instruction regarding a communicatively-relevant grammar feature after learners have attempted to use the language. This may perhaps involve drawing explicit attention to a feature that appeared to have been consistently or largely misapplied when learners engaged in interactive classroom-based activities, and using this feature in subsequent isolation from the communicative interaction as a focus for whole-class teacher input. Valeo and Spada (2016), for example, argued that each approach (integrated and isolated) is valuable for L2 acquisition, asserting that “recognition of the value of both approaches is consistent with research and theory claiming that each option may play a different role in L2 learning” (p. 329). This does not preclude the judicious use of grammar practice exercises, which may serve the function of consolidation.

Teachers may also perceive the need, from time to time, to provide direct instruction and practice in particular TL features in *preparation* for communicative activity. Thus, grammar might also be attended to explicitly through some form of direct teaching or instruction, alongside discrete practice. This replicates some dimensions of an FonFS approach or the PPP sequence. However, provided that the grammar being attended to is directly relevant to the communicative goals the teacher has in mind, there may be value, at least for some learners, in this initial top-down, teacher-led strategy.

East (2018) suggested that one way of achieving direct instruction that does not compromise plentiful in-class opportunities for L2 learners to use the TL creatively, meaningfully, and collaboratively is to “flip the classroom.” In a flipped classroom model, direct teaching can be facilitated by, for example, “finding or creating short instructional videos that carefully introduce relevant grammatical principles, coupled with practice material that helps learners to consolidate their learning” (p. 114). East concluded that getting the most benefit out of learning in the classroom will require a balance between language instruction and language use (or, teacher-led and learner-centered moments). A flipped classroom model “does not negate the need, from time to time, for explicit instruction, but capitalises on opportunities for meaningful interaction by relegating much of the preparatory work to outside the class” (p. 116). Also, giving learners a good deal of ownership for their own learning means that opportunities are provided for them to work both collaboratively and independently. (Certainly, as teachers across the globe become more familiar with online formats for language instruction as a result of COVID-19, teacher expertise in online asynchronous [not in real time] teaching is growing, and more imaginative and creative ways of providing learners with crucial input are emerging.)

When it comes to fluency versus accuracy, the reality remains that finding the most appropriate balance between meaning and form is challenging. Long (2015a), for example, argued, “[t]he jury is still out on optimal uses and timing of various kinds and combinations of instruction (explicit, implicit, focus on form, focus on forms, etc.)” (p. 26). Certainly, theoretical frameworks for optimal learning (as outlined earlier in this article) are important and should be taken into account. At the end of the day, however, the context will be a crucial element in teachers’ decision-making. This reality may be unsettling for teachers who may wish to have more robust theoretical guidance on optimal conditions for learning. The teacher remains nonetheless “the expert on the local classroom situation, after all” (Long, 2000, p. 188). Teachers know their contexts, their classes, and their students, and, as Thomas and Brereton (2019) expressed it, often just “prefer to *get on with it*” (p. 276) and “go with their own instincts regarding what works” (p. 278). Eclecticism in practice, albeit informed by the theoretical standpoints and arguments presented here, provides the space for this to happen.

Conclusion

The purpose of this article has been to trace the historical development of CLT in both theory and practice, with a view to highlighting some of the tensions that have emerged. Eclecticism in practice is the current reality in many L2 classrooms. Nevertheless, certain principles for maximizing learning have been drawn out from a consideration of sometimes contrasting theories of effective pedagogical practice.

In a recent article that acknowledged the considerable evolution and expansion of CLT since its inception, Spada (2018) argued that “21st century CLT” represents “a greater balance, scope and depth” (p. 12). This includes the interface between direct instruction and communicative practice in learner-centered classrooms that have been explored in this article. It must also be acknowledged that, even though principles such as input, output, and interaction appear to focus principally on the conversations that students might undertake in the communicative classroom, CLT is not just about speaking. CLT embraces a range of skills, which may well be integrated (e.g., responding in speaking to listening or reading input). Furthermore, there are some activities (such as writing) that can be undertaken collaboratively, but that also lend themselves particularly well to independent work, both in and beyond the classroom.

CLT also increasingly embraces the need for students to develop skills in negotiating cultural differences, or so-called *intercultural communicative competence*—a matter that is beyond the scope of this article (but see Walker et al., 2018, for some discussion of this). However, communicative interactions, particularly between L2 learners and L1 speakers, provide significant opportunities for noticing and negotiating cultural differences that may inform not only language choice (i.e., sociolinguistic competence) but also appropriate behavior, or taking into account in communication “the culture-specific context embedding the norms, values, beliefs, and behaviour patterns of a culture” (Alptekin, 2002, p. 58).

Spada (2018) concluded that L2 teaching and learning in today’s globalized world remains “important, indeed crucial work” (p. 12). As such, it is important to consider the factors and elements that are likely to optimize the learning of an L2 in the classroom, whatever the context.

Introduction

Youthful candy sellers, teenage Tik-tokers, online activists, aspiring artists, aficionados of writing, reading, and sense making in a plethora of community-based programs: these are the able learners and the thriving spaces, then and now, of learning and literacy out of school. Beginning three decades ago, and continuing to this moment, educational researchers have looked beyond the schoolhouse door in order to document, theorize, and celebrate learning (Hull and Schultz, 2002). The early studies showed how youth and adults regularly displayed competencies and motivations to learn and flourish in out-of-school settings, achievements that were not as visible in formal schoolrooms. These researchers asked why this was so, and they also wondered hopefully whether out-of-school practices, particularly digital ones, might be transported to schools with transformational results. The newer studies, especially those from the learning sciences that we feature here, likewise feature the accomplishments of learners out of school. But the recent work also tacks in different directions. And notably, this newer work in the learning sciences focuses on documenting learning everywhere, rather than focusing on whether and how these practices might inform learning in schools. In this chapter we chart some of the new conceptual pathways on learning every day and everywhere in out-of-school contexts that seem to us the most promising.

The early days of research on learning out of school yielded striking and important conceptual advances. In studies of literacy, for example, examinations of reading and writing in specific communities revealed a plurality of meaning-making practices and literacy's situated nature, shaped by socio-political, cultural, and institutional contexts (i.e., Heath, 1983; Scribner and Cole, 1981; Street, 1984). It turned out, notably, that school-based literacy is just one kind of reading and writing in a universe of many kinds, and this theorization itself represented a dramatic conceptual breakthrough, one that beckoned an ethnographic flowering, as literacy researchers embraced the invitation to characterize reading and writing as particular practices in multiple community, activity, and identity contexts (e.g., Barton and Hamilton, 1998; Heller, 1997; Kalman, 1999; Moss, 1994). "Out of school" was therefore a salient category in the early research, even as the kinds of learning done in such out-of-school contexts continued to play second fiddle to the kinds of learning done in school, where academic literacy and school-based knowledge, demonstrated through testing and accountability regimes, continued to hold sway.

The intervening years, however, have seen important shifts in this regard. Due in large part to the digital revolution, especially the rise of social media and the proliferation of mobile electronic devices, opportunities to socialize, create, communicate, teach, and learn have proliferated, as have digital platforms and spaces that host and afford such activities (Mills, 2010). Gone are the days when schools, even institutions of higher learning (Christensen and Eyring, 2011), had a monopoly on the transmission of knowledge and the socialization of learners. Learning happens all the time and everywhere, and increasingly learners have options; they are able to pick and choose their knowledge purveyors. What this means for research on learning out of school is that it is more important than ever before to shift our focus from schools as the only—or sometimes even the primary—site of learning, to recognizing and supporting the learning that takes place in and across a wide range of contexts, those carefully crafted by educators and researchers, and those that are more spontaneously constructed by children, youth, and adults. In addition, this new understanding of where, when, and how learning occurs provides new theoretical insights into literacy practices and education more broadly.

In this chapter we feature research on out of school learning that is informed by the learning sciences (cf., Nasir et al., 2020a). Doing so allows us to foreground insights about learning that arise from methodological innovations and theoretical directions, considerations that are especially salient in out-of-school learning. However, it is important to note that research on learning and literacy out of school is alive and well in various fields. As they have for many years, youthful desires and capacities to engage with digital tools continue to fascinate media researchers, who find fertile ground in such activities for exploring the development of creativity through, and criticality toward, popular media (e.g., Kraxenberger and Lauer, 2022). With the ubiquity of platforms like Twitter, new kinds of social (e.g., Marwick and Boyd, 2011) and political activity have emerged, such as hashtag activism (Jackson et al., 2020), which has proven of keen interest to researchers in multiple fields. Whole new industries have grown up around the provision of online learning, which promises the certified outcomes of formal schooling minus traditional time, space, and

attendance requirements (Impey, 2020). Such forms of non-school or extra-school learning have attracted the interest of university researchers, but also the corporate world of ed tech, which has designs on doing educating better than schools (Houghtelling, 2021). In the realm of play, identity experimentation, fantasy, and role play, which afford learning and development of myriad kinds, virtual worlds lead the parade for researchers intent on exploring the newest forms of technological meditation (i.e., *Journal of Virtual Worlds Research*). It is no accident that many of our examples connect to the digital, for this modality has claimed the lion's share of interest from out-of-school researchers for several years. Nonetheless, we also note that there remains abundant interest in forms of learning and development out of school that are not primarily mediated by the internet or digital tools: think dance, sports, and other kinds of embodied engagement (Katz, 2013) and imagine them in the context of after-school programs, a space that was an early focus of research on out-of-school learning and one that continues to thrive.

We are curious about how the current research in the learning sciences has brought new ideas into the discussions and research, in the past designed primarily by anthropologists and literacy scholars, that have documented the plethora of literacy practices across a wide range of contexts. We begin this chapter with a brief discussion of social design experiments, a central methodological approach used by researchers in the studies we review. As with current research on literacy in out-of-school contexts (e.g., Schultz et al., 2016), much of the latest research in the learning sciences is grounded in social and cultural theories. In addition, there is a focus on learning across time, place, and context, and on the movement that propels the learner across these contexts. Nasir et al. (2020b) remind us that learning takes place over time and across a lifespan, and through participation in a range of activities in both formal and informal settings. At the same time, they argue that people are differently positioned to have access to this range of opportunities for learning (Nasir et al., 2020b). Introducing the concept of learning pathways, they explain:

We conceptualize learning as occurring along culturally organized learning pathways—sequences of consequential participations and transitions (Beach, 1999) in learning activities that move (or do not move) one towards greater social recognition as competent in particular learning domains and situations (p. 195).

Nasir and her colleagues focus, as well, on the ways that learning pathways are intertwined with identities that affect how the pathways are determined, accessed, and resisted.

New methodologies

This emphasis on examining everyday activities as sites of learning—taking a walk, cooking a meal, playing a game—leads to the use of different research methods from those often used to document the learning that takes place in out-of-school programs, which has characterized much of the literature on out-of-school literacies and learning (e.g., Hull and Schultz, 2002). Rather than viewing programs or communities as sites for rich descriptions of youth's accomplishments in out-of-school activities, the more recent research in the learning sciences often leans on design-based research or research focused on the design of opportunities for sustained learning. Gutiérrez and Jurow (2016) introduced the method of social design experimentation that emphasizes the importance of co-designing projects with participants, focusing on justice and equitable learning opportunities that are available for youth from marginalized or non-dominant communities (See also Gutiérrez and Vossoughi 2010; Bang et al., 2016 provide a discussion of community-based research design.) Importantly, social design experiments seek to transform social institutions (Gutiérrez and Jurow, 2016) and re-imagine possible futures (Gutiérrez et al., 2020). Gutiérrez and Jurow explain:

Of significance is that social design experiments' explicit focus on disrupting educational, structural, and historical inequities through the design of transformative learning activity provides openings for learning, a context of critique for resisting and challenging the conditions that create and sustain inequities, and a space for generating their possible solutions. (p. 4)

As a result, social design experiments highlight the notion that participants are partners in the research, who have agency to design opportunities for their consequential learning in dynamic contexts, while participating in changing their futures. More recently Gutiérrez et al. (2020) have envisioned this design-based research along utopian lines, emphasizing the importance of seeing promise in everyday practices, in order to design new and more equitable and just forms of education for the most vulnerable communities.

The use of design-based research in learning sciences opens up new ways of describing and understanding learning. In what follows, we describe a few of the nascent themes we have observed in this literature that add to our understandings of learning in informal and out-of-school spaces. We begin with a discussion of the centrality of racial justice, power, and politics in these research studies. Equity and justice are at the heart of these studies of learning. Next, we explore the ways learning is documented as movement across space and time. Finally, we describe the ethical turn recently taken in studies of technology and learning.

Foregrounding racial justice and power

In our review of the recent studies of out-of-school learning in the learning sciences, we are struck that racial justice and power are foregrounded in new ways in many of the studies. While in the past, researchers often located their investigations in marginalized communities and thereby called attention to inequities as well as the creativity and potential of “underserved” youth, the newer work in the learning sciences takes an explicit stance toward advancing justice and social activism, highlighting BIPOC communities. For instance, [Barajas-López and Bang \(2018\)](#) situate their study of an Indigenous STEAM program in “the history of colonialism and the intended erasure of indigeneity through the world” with a goal of “creating equitable and transformative learning (p. 7).” Their work underscores what [hooks, 1990](#) describes as the possibilities for imagining learning from a position of marginality and oppression. hooks introduces the concept of radical openness as “a generative space for freedom, a space alive with continual engagement, play, and the re-making of cultural and historical relations that can create flourishing ways of being and becoming,” explaining that this type of learning is fundamentally about acting in the world with care and compassion (p. 150). Putting these ideas into practice, [Jurow and Shea \(2015\)](#) describe their project connected to the food justice movement as designed for radical openness and possibility ([Gutiérrez et al., 2020](#)) in order to make visible the ways people make decisions shaped by power and authority. [Gutiérrez, Jurow, and Vakil \(2020\)](#) write, “The shifting nature of our research and designs was a mirrored response to the shifting nature of injustices facing the community (p. 341).” Politics is explicitly situated in this research, which documents a political movement. Its form, message, and findings are all political.

In their introduction to a special issue of the *Journal of the Learning Sciences* focused on learning and collective action, [Curnow and Jurow \(2021\)](#) explain: “The kind of work we are advocating calls for a distinctive set of interventions, embedded in collective action that is anti-racist, anti-colonial, queer, feminist, anti-ableist, abolitionist, and that makes justice possible and inevitable.” Their identification of this wide range of groups and their explicit framing of this work around advocacy signals a shift in both theory and practice in the learning sciences and adds to our knowledge of informal learning. Their centering of justice as method as well as context leads to new practices and new understandings about learning and learners. This discussion of learning through political engagement is explicitly tied to learning in everyday life and seems less committed, especially in comparison to earlier studies, to finding a way to bring this way of learning and knowing explicitly into the classroom.

An example of work that centers justice and politics is a study conducted by [Tivaringe and Kirshner \(2021\)](#) that traces the learning that occurred during the growth of a local activist group in South Africa as it became a social movement. The authors describe how members of this group—Equal Education (EE), an organization committed to expanding access to quality education—participated in a range of activities, including reading circles and participating—or in some cases apprenticing—in political activism such as campaigns. One youth described how her participation in a campaign helped her to learn that there were a range of ways to engage in electoral politics, from voting to civil disobedience. The authors conclude that their study illustrates the ways that youth learn how to navigate contentious political moments and wield political power through the participation in multigenerational groups. Their research illustrates a particular form of learning that includes organizing and leads to political change. The authors clarify that the youth participants likely gained this knowledge by apprenticing with more experienced participants through the Equal Education group. They further explain the ways that this learning occurred not only in the courthouses and on the streets, but also through social media and other online spaces. At the same time, the learning that took place in these meetings and actions does not resemble school learning nor could it take place in that context.

Learning on the move

A second theme salient to conceptual advances in learning is the recent interest in studying “learning on the move” (e.g., [Marin, 2020; Marin et al., 2020](#)). This work emphasizes the spatial and temporal dimensions of learning in everyday contexts, including relationships between humans and nature. In their study of learning through walking together, [Marin et al. \(2020\)](#) explain that a focus on mobility in learning, or learning on the move, allows us to reconceptualize nature-culture relationships. Rather than studying learning in specified places or programs, whether in classrooms, after school programs, or in homes and communities, these authors examine how learning occurs in specified locations or during particular events, as well as during the movement between them. In contrast to the typical understanding of context as place, [Marin and Bang \(2018\)](#) describe context as temporal. In addition, they illustrate how the process of walking, reading the land, and exchanging stories (or storying) leads to deep learning about the natural world as well as understanding how a person (child or adult) is situated in the world. They explain further that this way of knowing reflects Indigenous epistemologies that have been practiced for generations (see also [Brayboy, 2005](#), for an early discussion of TribalCrit or Tribal Critical Race Theory.)

In their introduction to the *Handbook of the Cultural Foundations of Learning*, [Lee et al. \(2020\)](#) elaborate the Indigenous epistemologies that animate current theories of learning:

Operating from epistemological and ontological belief systems that center the well-being of the self, family, the community, the land and waters, the spirits, and the ancestors, these traditions view human learning and development within a framework of connectedness, embeddedness, and reciprocal relationships with all things past, present, and future (p. xxv).

In a study that illustrates this work, drawing on indigenous epistemologies, [Marin and Bang \(2018\)](#) describe the ways a mother and her son “story” the land, while walking in an urban setting and investigating through talk whether the water they observe is indeed a river. Marin and Bang describe this process of learning, explaining:

[I]t is another example of epistemological navigation where mother and son use questions and directives, as well as embodied moves, to open and close spaces of wonder and inquiry. They also rely on evidence both from the field and past experiences, knitting together landscapes to consider systems that are present in multiple places. Also, the mother’s use of tentative language provides an opportunity for Jason to be a coconstructor in knowledge building and provides openings for him to offer both his disagreement and his own ideas (p. 111).

The authors explain that the learning occurs between people in relationship to the land and water or between humans and more than humans.

A recent study by Taylor provides another example of learning on the move. Introducing the term “locative literacies”, [Taylor \(2017\)](#) traces the learning of youth as they tracked their pathways through a designed task that used global positioning system software (GPS) in order for youth to produce their own maps to use in conversation with policymakers (See also [Taylor and Hall, 2013](#)). As [Taylor \(2017\)](#) explains,

Learning along lines is a kind of participation framework ([Goffman, 1981](#)) or “fluid structure of mutual engagement and disengagement” ([Jordan and Henderson, 1995](#), p. 67) that organized bodies, technologies, maps, and places along lines that youth read, talked about, walked, drew, gestured, and examined (p. 535).

Through her research, Taylor expands notions of embodied learning. She explains that the notion of learning along lines—or learning through moving across the city, reading and writing its contours, and recording insights—highlights how people can be part of the text rather than simply recipients or producers of that text. In order to capture this embodied learning, Taylor produced multimodal transcripts that weave together talk, body position, gaze, gesture, and the larger context, including tools, in order to glean new insights about learning that is not bound by time and place, but instead traces the movement of youth across a city. Taylor writes about how this process of learning along the lines created opportunities to engage in new forms of digital literacies with mobile and location-aware technologies, such as GPS. This process was both embodied and understood through the youth’s own narratives and experience with the place where this learning occurred. Rather than seeing the youth as either consumers or producers of texts, Taylor describes the ways that they are a part of the text, thus affording new understandings and learning. Ultimately, the youth were able to use their knowledge gained from this project to inform the urban community mapping process, sharing their insights with urban planners, cartographers, and city government officials.

What strikes us about these examples of political activism and learning on the move, is that they illustrate opportunities for learning that do not exist in school or school-like programs. Furthermore, they are not examples of learning in service of schools (or for school-learning) nor are they examples of the kinds of learning schools might replicate or count. Each of these examples has equity and justice at its center. They are examples of how opportunities for learning can be designed to engage learners in new ways, through new modalities, as well as in everyday activities.

Ethical dimensions of technology

Much learning and doing out of school, both past and present, is mediated by digital tools, platforms, and socio-technical systems. Famously, such learning and doing have privileged—during the last two decades—creative, productive activities. Whereas decoding or viewing or comprehending text was the quintessential activity that distinguished literate participation during the last century, it is the creation and production and circulation of texts, including multimodal ones, that is increasingly today’s literate calling card, particularly out of school (cf. [Brandt, 2014](#)). And even more expansively, creative production fueled by the affordances of digital media also increasingly includes the design of platforms and applications through learning to code, instead of just textual artifacts ([Peppler and Kafai, 2007](#)). The rallying cry has thus become youth as makers, not only consumers of technology, and so we witness youth-created video-games and robots, as well as artistic remixes, mashups, and memes. This creative, productive, digitally-mediated activity and learning typically lives in community centers, hacker spaces, homes, media labs, and on the move as youth and everyone carry and deploy their devices in intersection with geographic and social spaces. Documenting, analyzing, theorizing, and supporting such activities are still important foci for research on out-of-school learning and doing.

Still, our review of recent studies of out of school learning associated with the learning sciences has also revealed a new and important focus around youth’s associations with technology that we wish to highlight here, and it takes an ethical turn. Specifically, there is growing interest in creating learning environments and harnessing digital tools in support of youth’s engagement with the moral and ethical dimensions of technology. [Vakil and McKinney de Royston \(2022\)](#) helpfully provide three broad categories for characterizing educational motives for using technology. The first promotes digital and media literacy by emphasizing youth as sophisticated users of technology, able to comprehend and consume digital content. The second privileges making, whether designing technologies or creating digital artifacts, as we discussed above and identified as the major approach toward digitally

mediated learning out of school during the last two decades. The third category prioritizes critique and positions youth as “critical agents of technology” (p. 4). While this approach appreciates the importance of youthful identities as makers, it has a critical edge, whereby technology is mastered toward social justice ends. That is, “learners are supported to use, manipulate, and create technologies that subvert power” (p. 4), and in “decoding technology’s relationship with power” (p. 1).

For a long time, many have felt a moral compulsion to put technology in the hands of minoritized and underserved youth, contributing thereby to leveling the playing field and addressing material inequities. There has been a commitment as well to giving youth access to powerful digital media practices, whether digital storytelling or coding, and thereby supporting their agency as makers and communicators. But often, this work has not explicitly foregrounded the ethical implications of technology use—that is, “learning how to decode and unmake tech’s relationship with power through artistic, moral and humanistic inquiry” (Vakil and McKinney de Royston, p. 2). This is the approach that Vakil and McKinney de Royston advocate and that they illustrate through the Young People’s Race Power and Tech Project (YPRPT), a community-university partnership in Chicago where high school students, community educators, undergraduates, and computer scientists jointly investigated how artificial intelligence and big data technologies were affecting minoritized communities in Chicago. During a summer workshop and a year-long after-school program, students explored facial recognition technology and other advanced technologies with an eye toward how they were operating in their own communities. They also produced documentaries that explored the ethical and technical dimensions of the technologies. In their article, Vakil and McKinney de Royston feature their analysis of a documentary film produced by two youth to explore how ICE used facial recognition software to monitor social media accounts and to surveil public areas in their communities, with the end result of detaining, deporting, and criminalizing immigrants. The authors refer to the students’ work as “philosophical sensemaking” (p. 9) and demonstrate how they combined personal narration and political inquiry to artistic and rhetorical advantage.

Among the windows opened by this provocative effort to position youth as philosophers of technology is a fresh look at what constitutes generative outcomes where learning about and with technology is concerned. Historically, out-of-school or afterschool programs were taken to task if they were not able to demonstrate gains in school-based skills as demonstrated by conventional measures, such as reading comprehension scores. Vakil and McKinney de Royston, and their collaborators at YPRPT throw off these shackles and make a compelling argument through their data, following [Bang and Vossoughi \(2016\)](#), about the importance of growth in relationality as an important goal and outcome. It turned out that the young people who are featured in their research and the YPRPT program built strong relationships with each other over the course of project activities, which in turn revealed the interconnections between relationality and the understandings the youth came to about technology, race, and power. In fact, they argue that a pedagogical design that centers the development of racial and political solidarity is a prerequisite for the kind of ethical sensemaking around technology they hoped to foster. But, on the flip side, Vakil and McKinney de Royston also show that relationality can itself be an outcome of ethical sensemaking. Grappling with content around the interconnections among race, power, and technology, contextualizing their work in the current historical moment of a national reckoning around systemic racism, bringing their burgeoning understandings to bear in the creation of a documentary—all of these activities likewise deepened their relationships with each other, the strength of their connection to social issues, and their nascent theorizations of the impacts of technology in today’s world.

Another study that foregrounds the ethical dimensions of technology, this one set in India, is [Hull et al. \(2021\)](#) design-based exploration of a virtual reality storytelling exchange. Drawing from a critical account of cosmopolitanism, their essay theorizes young people’s rights and capacities to speak, listen, and be heard in a global world and, in tandem, it explores the communicative power and human reach of new forms of storytelling. The study demonstrates that it is indeed possible to design learning spaces that mitigate communicative and representational inequalities and where young people learn to communicate and imagine across semiotic, cultural, and geographic divides. It also examines the challenges surrounding such acts of trust and imagination and emphasizes the importance for youth of developing and exercising capacities to “world the world”—to represent their own lived experiences in relation to understanding the lived realities of others. These acts of perspective-offering and perspective-taking, the authors claim, are quintessential critical cosmopolitan capacities for a global era. Especially important are the linguistic and semiotic aspects of these imaginings, seen in the ways that youth world their worlds by marshaling symbolic resources that cross and blend languages, modes, and media ([Canagarajah, 2013](#)) and that transcend logocentric notions of texts ([Lizárraga et al., 2015](#)).

Conclusion

As we write this chapter, a global pandemic, that has lasted several years and continues to persist, has shaped education and lives. The experience of loss is top of mind as we enter a post-Covid time (though that term remains contested), the loss of lives uppermost, but also the loss of jobs, mobility, sociality, and, for educators and families most poignantly, the loss of opportunities to learn. Indeed, “learning loss” is now a ubiquitous term at every level of schooling, as analyses reveal that a consequence of a world-wide pandemic is that children fell behind in mathematics and reading, gaps widened in achievement and opportunity, and long-standing inequities increased. This is a picture of an apocalyptic educational landscape, the contours of which we acknowledge, even as we also aspired in this essay to offer a different vocabulary for describing it and some distinctive strategies for addressing it. If, as research suggests, we understand that people are engaged in learning all of the time and in a wide variety of contexts, then we should clarify that what was lost for some children was specifically school learning. Learning certainly occurred during the

pandemic when students in the US and other countries were confined to their homes. However, it was learning that is not typically accounted for in schools. Rather than a focus on the learning losses during Covid, we urge educators, parents, and caregivers to notice the learning that did happen and build on that knowledge. This might also lead to funding community-based, youth-initiated learning in response to “learning loss”, as well as summer schools that replicate school learning. The new work on learning, such as the research we feature in this article, helps us to notice and understand these new and potentially powerful types of learning.

In their outgoing editors’ note for *The Journal of Learning Sciences*, the signature journal for the field, Radinsky and Tabak, 2017 recounted their accomplishments during their term as editors. Among other changes to the journal, they mentioned that: “[t]he retirement of the Learning Outside of School strand at *JLS* corresponds with an increasing diversity of contexts in which learning scientists study learning—such that outside of school is no longer seen as a necessary descriptor.” While we understand the direction they point us toward—that learning occurs everywhere and the previous containers of “school” and “out-of-school” may be limiting in our current times—we argue that it is important to pay attention to out-of-school spaces, as well as everyday learning in order to deepen our understanding of the ubiquity and variation of learning.

The research we reviewed in this chapter reveals that learning outside of school—across space, time, and contexts—is flourishing. The studies we describe, as well as countless others, illustrate the promise and power of new contexts for learning. In this research, we have witnessed youth learning together in programs connected to schools or embedded in communities. We also offer research that documents the explorations of youth learning with family members and on their own. We were particularly taken by the multi-generational examples where youth learned as they participated in political campaigns and other forms of activism. And while the current research hones our vision and allows us to see learning everywhere and as a part of daily life, it also suggests new questions and research directions about other kinds of learning we should look for in the future and document as researchers, educators, and community members.

We conclude with some of these questions that might guide our inquiries into how learning transpires in the future. We know that many youth across the world are enraged about global climate change and the deteriorating planet and are seeking to make their voices and opinions heard. As youth engage in activism, in multigenerational groups, and on their own terms, as well as through their own invented routines and rituals, what are the contours of their learning? We know that the learning connected to social and political movements is generally not connected with school (and often students explicitly leave school to do this work), we wonder whether and how this learning is connected with school knowledge, while at the same time asking whether that question is even important? A second question that comes to mind concerns the connections between belonging and learning. As preK-12 schools, universities, and organizations seek to diversify their institutions, the notion of belonging, especially for minoritized students, has become critical. How do we understand belonging and identity as intrinsic to learning, and how do we construct educational environments, including online spaces, where learners feel they belong? We wonder, as well, how our understandings of learning will change as new technological advances offer new opportunities for exploration, experimentation, and the development of new knowledge. In tandem, what guardrails can we build as misinformation flourishes via social media and threats to privacy and equity abound through algorithmic bias in an AI world? What might and what should learning every day and everywhere look like in the future, when that future includes virtual worlds? We live in a precarious time, characterized by distrust and, throughout much of the United States, a loss of faith in the future of the democratic foundation of the country. What does this sense of despair and hopelessness mean for how we understand needs and opportunities for learning? And how might a focus on learning as it occurs every day and everywhere lead us toward hope and possibility?

Learning through work

Throughout human history, across continents and cultures, most occupational skills have been learned through experiences in workplaces, in ways quite distinct from what occurs in educational institutions (Dorman, 2012; Eraut, 2007; Roodhouse, 2007). These capacities have been learned by workers, rather than being taught by others (Rogoff, 1990). Understanding how learning arises through work requires explanatory premises about, and conceptions of, this phenomenon. Yet, these explanations need to be premised on workplaces as sites of learning, not those used to explain the practices and outcomes of educational institutions (Berryman, 1993; Billett et al., 2018b; Tynjala, 2008). This distinction is critical as there are important lessons here for addressing both the initial preparation of occupational capacities and their ongoing development across lengthening working lives. A fundamental difference in these explanations is that this learning and advancing of occupational practices have arisen through processes primarily based on individuals' active processes of learning, not through teaching by others (Webb, 1999). These processes have been essential for human survival and the progress of human cultures in the past (Donald, 1991; Jordan, 1989), and are likely to remain so in the future.

Across human history, local workplaces have been the sites for this learning: in Europe (Greinert, 2002), India (Menon and Varma, 2010), Japan (Singleton, 1989), China (Ebrey, 1996), Greece (Lodge, 1947), Mesopotamia (Finch and Crunkilton, 1992), and, likely, elsewhere. These sites and processes have been central to meeting the needs and wants of humans across diverse cultures and continents. In Europe, family-based occupational preparation was displaced only by industrialization (Greinert, 2002), a situation repeated elsewhere such as in China (Gowlland, 2012). The evidence suggests that this learning has arisen largely through individuals' participation in occupational practice, their active mediation of what they experienced, and processes referred to as mimesis (Byrne and Russon, 1998) or mimetic learning (Billett, 2014). The learning is that arising through individuals' active engagement in observation, imitation, and practice, not through being taught (Marchand, 2008; Singleton, 1989). This situation can be difficult to comprehend in contemporary schooled societies, where experiences in and through educational institutions are taken as the most accepted and effective sites for learning, and with that learning being premised upon teaching (i.e. the passage of knowledge from a more informed to a less informed person). This sometimes leads to teaching and learning being seen as synonymous. Such a view would have been inconceivable prior to the era of modernity and industrialization and the development of schooled societies. Before industrialization, only a tiny percentage of the population would have attended schools or other educational institutions and the focuses of much of those educational programs would have been far removed from developing occupational expertise, nor would they have been attended by those who would be interested in that kind of practice.

Consequently, it is important to identify and articulate premises and concepts that can explain how this learning occurs. Proposing premises and concepts that are distinct from those that are orthodox makes it even more important to be clear about how we should understand and appraise workplaces as learning environments, through carefully introducing, discussing, and advancing these precepts. These elaborations also offer ways to consider how the securing of occupational capacities can progress in contemporary times and are introduced below. Then, drawing on anthropological, historical, psychological, and sociological disciplines, considerations of the kinds of curriculum, pedagogic, and personal practices supporting learning through work are advanced. Firstly, models of workplace curriculum are explained and illustrated as pathways of work activities along which novices and newcomers can progress. Then, some examples of practice pedagogies are offered as a means of augmenting experiences in work settings. These are nothing more or less than affordances (invitations to engage), and their effectiveness in supporting learning is premised on the personal epistemological practices of the workers and students who participate in and learn in the circumstances of work.

Explaining learning through work: premises

Some of the concepts advanced above go against much orthodox understanding about learning through educational programs. This includes the privileging of accessing and learning the knowledge required for work through practice, rather than being taught (Dornan, 2012; Eraut, 2004; Tynjala, 2008). So, it is important that some explanations are advanced. These are four-fold. Firstly, the knowledge required to be learned for performance at work comprises the occupation's domain-specific conceptual, procedural (Stevenson, 2002), and dispositional knowledge (Perkins et al., 1993) and these have:

- canonical (occupational) and
- situational (workplace) levels (Billett et al., 2018a,b).

The canonical knowledge is what would be expected to be possessed by all individuals who practice a specific occupation. Accounts of that knowledge are often captured as statements of professional competence and goals and content for educational programs. Beyond the canonical occupational knowledge are the specific requirements of workplaces that require a situated manifestation of that occupational knowledge. The canonical occupational knowledge is that associated with studies of expertise, which is often viewed as the individual possessing comprehensive, well-structured and organized knowledge of that domain (Glaser, 1984). However, it is also noted that the key quality of expertise—being able to resolve nonroutine problems—also has a situational requirement (Billett, 2001a,b,c). The tasks a mechanic does in an inner-city vehicle dealership may be quite different from the work of a mechanic in a small country town or regional center. From their engagement in work activities such as these, individuals construct the instances of knowledge they encounter as personal domains of occupational knowledge (Billett, 1999). Their personal structuring of that knowledge will be shaped as occupational domain-specific:

- conceptual knowledge—“knowing that” (Ryle, 1949) i.e. occupational concepts, facts, propositions—surface-to-deep conceptual knowledge (Glaser, 1989);
- procedural knowledge—“knowing how” (Ryle, 1949; i.e. how we achieve goals through thinking and acting [both specific and strategic occupational procedures]; (Anderson, 1993; Stevenson, 2002; Sun et al., 2001); and
- dispositional knowledge—“knowing for” (i.e. values, attitudes) related to occupational and situated instances of practice (Perkins et al., 1993), including criticality.

Respectively, these three forms of knowledge represent what we know (conceptual), can do (procedural), and value (dispositional).

Secondly, there is no separation between engaging in activities—such as work—and learning (Lave, 1993). When we engage in everyday goal-directed activities we are also learning micro-genetically, or moment-by-moment (Rogoff and Lave, 1984). When we undertake tasks that are familiar to us, we refine and hone what we already know, can do, and value. When we engage in activities that are new or novel to us, we generate new knowledge and, potentially, ways of knowing. Moreover, the work activities and interactions in which we engage change constantly (Darrach, 1996). Across all kinds of social settings our activities are generative of learning, albeit of different kinds and innovations as we revise them. Importantly, that process also comprises the remaking of occupational tasks, as individuals engage in work activities in particular settings and respond to specific problems (Billett et al., 2005). Most often, that remaking is about adapting what we know to changing circumstances; however, it can also be transformational when novel responses are required for emerging problems or workplace tasks. So, as we engage in work activities, there are two legacies: learning, and the remaking of occupational practices.

Thirdly, the knowledge that needs to be learned arises from these interactions, yet is itself a product of history, culture, and situation (Scribner, 1985). The process of accessing, engaging, and remaking that knowledge occurs through inter-psychological processes: between the person and the social world (Wertsch and Tulviste, 1992). What is suggested here is that these processes are characterized by interdependence (i.e. the reciprocal engagement between individuals and the world in which they engage).

Fourthly, the richness of these learning processes is premised on the duality between the kinds of interactions and activities that individuals are afforded (Fuller and Unwin, 2004), and on how individuals elect to engage with them (Billett, 2001b). Consequently, it is more than the provision of experiences that is important, but also the interdependence between what experiences are afforded, and the individual engaging in and with those experiences. This is the duality which comprises workplace performance and individuals' engagement.

A program of research has identified these affordances as being four-fold, and each makes contributions to learning through everyday work activities that have been identified to include:

- (i) engagement in work tasks (“just doing it”)—legacies of goal-directed activities (cognitive and socio-cultural constructivist accounts);
- (ii) indirect guidance provided by the setting (“just being there”)—observation and imitation (cognitive and neuro-science accounts);
- (iii) practice within that setting—practicing, rehearsing, refining, and associating (cognitive accounts of procedural and conceptual development); and
- (iv) close guidance (proximal) by other practitioners and experts—assisting the development of knowledge that cannot be learned through discovery (Billett, 2001a).

Evident in this list is the key role played by the learners. Three of the four contributions are largely mediated by the learners, with only one—close guidance—being premised upon others' mediation of individuals' learning. Noteworthy is that it is incorrect to view affordances as always being constructive and helpful in shaping the required occupational practice: The same program of research also identified limitations of learning through practice through what has been afforded by workplaces. These include:

- learning that is inappropriate (i.e. bad, unhelpful knowledge and perilous ways of doing things);
- lack of workers' access to work activities and workplace guidance;
- workers not understanding the goals for performing tasks;
- reluctance of experienced co-workers/experts/supervisors to provide guidance to workers;
- absence of expert guidance in the workplace; and
- reluctance of workers to participate effortfully in learning (Billett, 2001a).

So, what is afforded workers—what is provided for them and they can experience—variously either supports or inhibits what can be learned through everyday work activities.

This section has sought to set out some of these premises to understand learning in and through work, and their similarities and distinctions with participating in experiences provided through educational settings. It follows that improving learning in the workplace necessitates trying to secure or enhance the contributions to learning that comprises the affordances of workplace experiences listed above and then attempting also to redress the limitations listed here. In the next section, consideration is given to how workplaces can be effective learning environments through curriculum and pedagogic practices, and learners' personal epistemologies.

Practice curriculum, pedagogies, and epistemologies

The practice curriculum comprises sets and sequencing of experiences through which individuals learn about their occupational practice. This relates back to the original meaning of the word "curriculum" which refers to the "course" or "pathway to progress along" (Marsh, 2004), as it comprises the sequence of activities that learners progressively engage in as they develop their occupational capacities. Pedagogic practices are activities or interactions that can enrich and augment learning arising from experiences in work settings. Note that the term "pedagogic practices" (Portisch, 2010; Tomasello, 2004) describes ways of supporting learning that go beyond teacherly processes (Fuller and Unwin, 2002). It includes those that arise through engagement in work activities and interactions and with artifacts such as partially completed jobs. An important element of workplace pedagogic practice is that it enables learners to access knowledge that they would not be able to discover on their own. Yet, these pedagogic practices are quite distinct from those enacted in classrooms. Then, there are learners' epistemological practices which comprise the basis on which individuals engage with, construe, and construct knowledge through practice (Billett, 2009). These are a product of individuals' personal histories and ontogenetic development (Scribner, 1985)—their repertoire of engagement in activities and interactions across their lives, and how these practices come to shape the ways in which they engage with what they have learned in their workplaces and how they learn from that process.

These three foundational components of learning through practice are likely to be enacted in tandem in most work-related activities. To illustrate these foundations and their interplay, consider this example of Sue, a third-year medical student (Billett and Sweet, 2015). Sue engages in a longitudinal clinical placement in a medical practice in a small town in regional Australia. For the first 6 weeks, she works alongside a doctor in her consulting room, largely observing how the doctor goes about her work. Along the way, Sue asks questions and the doctor provides explanations and sometimes questions Sue about her knowledge. Throughout this period the learning is based on mimetic processes of observation, engagement, and some practice. Being assigned to this doctor also means that Sue visits a hospital where the doctor works, and she comes to observe medical work in that environment. After 6 weeks, Sue is given a consulting room next to the doctor. Then, with the consent of patients, she engages in history taking and examination and arrives at conclusions about patients' health and likely remedies. At this point, the doctor engages to check the information as soon as it is gathered and to check the basis of Sue's prognosis. These are elements of practice curriculum: the progression along the sequence of activities that incrementally assist in developing learners' capacities to enact their occupation. Later, Sue wanted to know how to take blood from patients. From her experiences at the local hospital, she was able to identify a nurse who was competent in this. Sue then observed this nurse and engaged in episodes of practice so that she became competent in taking blood. In this way she exercised the processes that she had been subjected to, observed, imitated, and then practiced: all elements of mimetic learning.

As can be seen, Sue exercised her personal epistemologies in constructive ways: She asked questions, engaged intensively, and then was able to participate in procedures that allowed her to gain information and make clinical decisions. Along the way, she developed a range of procedural capacities; for instance, her decision to approach the hospital indicates the importance of agency interest. Beyond that, Sue actively engaged with the local community: Rather than returning to her home on weekends, she elected to stay and live in this town and to join the local church and the tennis club. Thus, she engaged with the community and her health care colleagues, which then allowed her to seek advice from the hospital and engage with hospital staff. Indeed, this interaction led to staff members phoning her when interesting cases were being considered at the hospital.

This example illustrates how the curriculum—the sequence of experiences that soon progressed, the use of pedagogic practices such as questioning, observation, and personal engagement—is generative of rich learning. In the next two sections, a brief outlining of practice curriculum and pedagogies, and learners' epistemological practices, is provided.

Practice or workplace curriculum

The literature on how individuals have learned through their work practices across history and diverse cultures suggests that there are two broad categories of approach. Firstly, there is what might be referred to as an apprenticeship as a way of life: learning through the lived experience of being in a community and engaging in its practices (Bunn, 1999; Jordan, 1989; Rogoff, 1990); that is, learning as part of growing up, all being embedded in cultural circumstances (e.g. the lived experience of work, such as family business, farm, or nomadic community). Secondly, there is the deliberate structuring of learning experiences to achieve certain learning outcomes (Bunn, 1999; Chan, 2013; Fuller and Unwin, 2003). The former is likely to be the model that has been dominant throughout human history up until the modern era, the advent of schooling, and preparation for occupations outside the circumstances of their enactment. Even today, in countries other than those with advanced industrial economies, these are the models that continue to exist for skill formation. However, within developed countries, the kinds of immersion in occupational practice that featured in earlier times (i.e. by living and working in the master's house and in a street full of similar workplaces) now rarely exist as a model for learning the capacities required for effective work. So, it is the second category of approach—the deliberate ordering of experiences—that is relevant to much of contemporary work. Helpfully, this ordering of experiences is very consonant with the original meaning of the word curriculum. What is evident in the literature is a range of models of workplace curriculum based upon different kinds of pathways.

Ordering of experiences: curriculum pathways of work

Perhaps the most well-known and acknowledged pathway is the sequencing of activities that move from novices engaging in activities in which there are few consequences if errors are made (low error risk) to those activities in which the consequences of errors are greater (high error risk) (Lave, 1990). Lave's study identified the progressions of tailors' apprentices based on this principle. Her work also identified the pedagogic qualities and intents in this sequencing, in many ways analogous to what occurs in educational settings (Billett, 2006). In my own work investigating the learning pathways of hairdressers, production workers, and room attendants, similar pathways were evident. Equally, a study of junior doctors indicated progression of activities and learning premised on this principle (Sinclair, 1997). However, not all curriculum pathways are based upon considerations of error alone. For instance, the stages or pathways associated with learning to be a potter are premised on access to artifacts (i.e. the potter's wheel) and materials (Singleton, 1989). Table 1 sets out different kinds of sequencing, including the approach that Sue experienced in her parallel

Table 1 Workplace curriculum practices—qualities and ordering of experiences for effective work and learning.

Practice	Description	Purposes
Apprenticeship as a way of life	Engaging individuals in the lived experience of workplaces by participating in their everyday activities and interactions (Bunn, 1999; Jordan, 1989) to understand the practices and requirements for performance (Lave, 1990; Makovichy, 2010).	Identifying goals for workplace performance and learning procedural and conceptual knowledge, including honing procedures, forming propositional associations, and developing strategic procedures.
Ordering of experiences	Providing access to and ordering of experiences required to learn occupational capacities not acquired through everyday work; might entail skill acquisition in stepwise manner from those easy to learn to those which are more difficult (Chan, 2013).	Offering a pathway of experiences through which occupational capacities (conceptual, procedural, and dispositional) can be developed.
Learning curriculum	Organizing access to work activities from those having low consequences when errors occur to those where costs of errors are high; starting with observations to understand goal states and progressing through increasingly demanding work requirements (Lave, 1990). In work where all components carry the same salience (e.g. midwifery, (Jordan, 1989) junior doctors, (Sinclair, 1997), learning might be acquired in a linear order.	Organizing a pathway of experiences whose ordering is based on pedagogic and practice-based considerations, such as increased complexity or error cost.
Learning activities as work conditions permit	Learning staged around workplace imperatives e.g. learning pottery premised on access to potter's wheel: (i) pre-practice observation with apprentice engaged in menial work activities, (ii) tentative experiments with wheel (when not used for productive purposes), (iii) assigned regular practice at wheel, (iv) assigned production tasks at wheel, and (v) a period of work to repay training (Singleton, 1989).	A pathway of experiences based upon access to other workers, equipment, resources, that bring together the imperatives of work, workplace, and learning.
Parallel practice	Individuals engaging in an occupational practice and being monitored and checked by a more experienced partner at key points in task completion (Billett and Sweet, 2015), e.g. doctors seeing patients, taking histories, and conducting examinations, often in parallel with what has been done by a registrar (Sinclair, 1997).	Opportunities to engage in authentic activities while being monitored and checked by a qualified practitioner.

practice. It presents models of workplace curriculum, a description of their characteristics, and the purposes which they can realize. Although far from comprehensive, the range of models here indicates that there are options for pathways depending upon the kind of work being learned and also the kinds of circumstances in which that work and learning co-occurs.

An elaboration of these models can be found elsewhere (e.g. Billett, 2014). Here, they are outlined to indicate the diversity of curriculum models that are a product of exigencies of work and workplaces and, by degree, that offer pathways of learning for workers. Yet, beyond a consideration of these curriculum models as pathways, there are other ways by which experiences in workplaces can be augmented to enrich learning; that is, practice pedagogies.

Practice pedagogies

As proposed earlier in this article, much of the learning required for work arises through individuals' everyday engagement in it and their work practices. These are what permit the process of ongoing development and expose workers to new challenges, from which novel learning arises. Nevertheless, the quality of that learning can be supported and assisted by interactions with others and by the clues and cues provided by artifacts and other sources of information (Fuller and Unwin, 2002; Ingold, 2000; Lave et al., 1984). These are referred to as pedagogic practices and, in so far as they are embedded within the conduct of occupational practice, they are referred to as practice pedagogies. The term "pedagogies" is used to capture more broadly the contributions, that assist and augment learning, and that go beyond those provided directly by more informed others (teachers, experienced workers, supervisors, etc.) through instruction, story-telling, and collaborative working. They extend to artifacts, such as tools and completed (Lave et al., 1984) or half-completed jobs (Makovichy, 2010), and to what can be secured through observing, hearing, and other forms of sensory engagement (Rice, 2010; Tomasello, 1998). These pedagogies are important for augmenting learning through work; in particular, for going beyond the circumstances that might otherwise be limited by individual discovery alone. There are limitations to learning through everyday work activities because not all knowledge is easy to access, or to comprehend when accessed. Certainly, a consideration for contemporary work is that much of the knowledge required for effective work practice is conceptual and symbolic (Barley, 1996) and, therefore, requires being accessed and learned in ways which make it more explicit and accessible (Harteis, 2018). With the increase in the use of electronic technologies, for instance, the kind of knowledge that used to be learned through sensory processes and engagement is becoming a lesser requirement as work tasks become less dependent on manual manipulation (Harteis, 2018). Instead, less accessible forms of conceptual knowledge are now becoming important to learn and need to be engaged with through symbols and other forms of representation that can assist individuals' engagement in and building representations of that knowledge. Hence, there is a requirement for pedagogies that can enrich experiences and support that learning. The word "pedagogic" is used here to encompass a range of contributions that can mediate individuals' thinking and acting in support of that learning. Often, there is a need to go beyond teaching or direct instruction, to identify practices which make knowledge accessible and engaging, particularly when related to the kinds of activities which can be learned and applied. The anthropological literature offers a range of pedagogic practices. For instance, the use of available artifacts (Pelissier, 1991) and the role of story-telling (Jordan, 1989) as a means by which a narrative provides a context, and a way in which individuals can engage in, remember, and recall what they have learned, are important contributions to individuals' mimetic learning. The process of verbalization (Gowlland, 2012) has a similar quality, as it makes the thinking of experts accessible to novices who can engage with what is being stated, then appraise it and relate it to their knowledge and ways of knowing.

Then, there are certain work activities that are pedagogically rich (Billett et al., 2018a,b); that is, they have inherent qualities that make them potentially potent as learning experiences. The handovers held by nurses and other health care workers are representative of these experiences. The ability to discuss, compare, and evaluate patients, their condition(s), treatment(s), and progress, and then to permit prognoses to be constructed, represents rich learning experiences because of the contextual nature of the activities, individuals' engagement in them, and the responsibility drawn from them. In addition, there is the close guidance that can be provided by more experienced workers when what needs to be learned is unlikely to be achieved through individuals' discovery alone (Billett, 2001a; Gowlland, 2012; Rogoff, 1995). Consequently, in those circumstances, engaging with more experienced co-workers, gaining more knowledge, and making that knowledge accessible can be crucial for learning "hard to learn" knowledge. Beyond direct guidance is that which occurs indirectly through observing, listening to, and otherwise indirectly engaging with more experienced co-workers and their actions and outcomes (Gowlland, 2012). There are also specific procedures such as heuristics or tricks of the trade (Billett and Rose, 1997; Sinclair, 1997) which are helpful procedurally for securing outcomes. In terms of conceptual development, mnemonics are helpful for providing reminders, cues, and devices to recall demanding and interrelated knowledge (Sinclair, 1997). Physical contributions can also come from the layout and qualities of the setting (Barker, 1978; Lave et al., 1984) and from being able to access cues and clues, such as partially worked or completed examples of the tasks that need to be accomplished (Makovichy, 2010).

In Table 2, some of these kinds of pedagogic practices are set out. They are listed in the left-hand column, described in the middle column, and their potential purposes are provided in the right-hand column. Again, what is evident is that these pedagogic practices are of different kinds, have distinct qualities, and can be directed toward different kinds of purposes; they are elaborated in other publications (e.g. Billett, 2014).

It will be noted that these pedagogic practices are quite different from those used in classrooms. This is an important distinction: Many teaching strategies and classroom pedagogies are founded on the exigencies of the physical environments of classrooms and their norms and practices. These environments are premised on and designed for instruction for large numbers of individuals

Table 2 Workplace pedagogic practices—activities and interactions that permit performance and enrich learning.

<i>Practice</i>	<i>Description</i>	<i>Purposes</i>
Storytelling	Telling stories about work events and incidents (Jordan, 1989).	Illustrating or capturing concepts or hypothetical formulations to assist in decision-making; legitimate practitioner as expert.
Verbalization	Talking aloud while performing a work task as a form of direct guidance, linked to “hands on” engagement (Gowlland, 2012).	Explaining the thinking and acting being used while performing work tasks.
Pedagogically rich activities	Workplace activities that are inherently pedagogically rich, e.g. handovers (Billett et al., 2018a,b) or case discussion, moderation, or planning meetings.	Developing conceptual, specific, and strategic procedural capacities.
Guided learning (proximal guidance)	Direct interaction between more and less experienced co-workers to promote learning in work settings. Use of modeling, demonstrating, guided practice, monitoring progress, and gradual withdrawal of direct guidance (Billett, 2000; Collins et al., 1989; Rogoff, 1995).	Extending what individuals can learn through discovery alone by modeling of activities to be learned, guidance to assist achieving modeled performance, and providing opportunities to refine and hone.
Partially worked example/direct instruction and hands on	Combination of guidance and using a worked example, e.g. experienced lace-maker producing a small piece of simple lace, showing novice how bobbins are held, and placing hands on those of a novice to assist learning hand movements to use the bobbins; also asking novice which bobbin they should use for the next stitch before novice makes movement, leading to confidence in action; questioning gradually ceasing as competence demonstrated (Makovichy, 2010).	Provision of models for performance, ability to engage in sub-skills associated with that performance and build understanding about procedural capacities.
Heuristics	Tricks of the trade (i.e. procedures that will give you certainty; Billett and Rose, 1997).	Developing procedural capacities through providing devices that assist in securing workplace goals.
Mnemonics	Developing and using mnemonics (doctors’ use of 5 Fs, DANISH, to remember about cerebellar lesions) and actual patients (“remember Mr Leeming and you will remember about duodenal ulcers”, Freddie Mercury and missed seroconversion) (Sinclair, 1997) for procedural efficiency (Rice, 2008, 2010).	A means to remember and recall propositions and secure procedural efficacy.
Artifacts	Embedding the knowledge required in a localized context to assist skill and proficiency (Makovichy, 2010).	Providing clues and cues on how to proceed.

positioned as students, probably modeled on church pulpits. Practice pedagogies, however, are associated with the social and physical circumstances of workplaces and the practices within them and, importantly, are embedded within the work practices to be learned.

These considerations of curriculum and pedagogic practices are what can be afforded to individuals through their workplaces and work activities. However, learning through social practices is premised on the duality between (a) what individuals have been afforded, and (b) how they elect to engage with what has been afforded. This suggests that the contributions, invitations, and affordances are nothing other than potential contributions to individuals’ learning and development. Ultimately, it is how individuals engage with that learning. Central here are individuals’ personal epistemologies that shape how they engage with what has been afforded to them.

Personal epistemological practice

As has been stated, it is insufficient to explain the contributions to and processes of learning through work by referring only to what is afforded by the physical and social setting in which workers engage (i.e. workplaces). Instead, understanding and accounting for this process of learning needs to go beyond what has been afforded and to consider how individuals come to engage with the ways in which they are invited to participate in, and learn through, work activities and interactions (Bauer et al., 2004). As noted earlier, throughout human history the vast majority of learning and development is likely to have arisen through individuals’ personally mediated learning: how they use what they know, can do, and value to construe and construct what they are experiencing. So, when considering individuals’ learning through work, it is important to acknowledge that it is shaped by individuals’ personal epistemologies (their bases for knowing, engaging, and learning) (Bauer et al., 2004; Billett, 2009).

The literature identifies a range of ways in which this personal mediation of experience and the legacies from it (i.e. learning and development) arise. These include what is referred to as imitation, which is held to be an important process for most kinds of

animals but, in particular, for humans, who have taken this process to a high level (Gardner, 2004; Jordan, 1989; Marchand, 2008; Tomasello, 2004). This process is consonant with the process of *mimesis* (i.e. observation, imitation, and action) and with what has been referred to above as mimetic learning, which goes beyond a reliance on observation and proposes that all sensory inputs play a role in human sense-making and learning. There are a range of strategies associated with the deployment of *mimesis* and one of these is referred to as ontogenetic ritualization (Tomasello, 2004). This concept refers to how two interlocutors engage with, and secure access to, what one needs from the other. Based on observations of orangutans, where babies negotiated with their mothers to gain access to the breast, this process has parallels in the way that humans negotiate with each other to gain access to partnerships, to shared activities, and to each other's knowledge.

However, given the personally mediated nature of this form of learning and development, the importance of learner readiness (Bunn, 1999; Singleton, 1989) has come to the fore. Readiness here refers to the level or capacity at which individuals engage in activities and learn from them. For instance, if individuals have no knowledge of a specific language or its grammatical structure, merely being immersed in a situation where that language is being used may not be a productive learning experience, because they are not ready to engage effectively. Furthermore, individuals need to assent to that engagement (Mishler, 2004). Only they will decide on the ways in which they will come to engage in the effortful process of constructing meaning, developing procedural capacities and developing further their values and interests. This is aligned with the process referred to as deliberate practice (Ericsson, 2006; Gardner, 2004; Sinclair, 1997): the effortful, intentional, and focused engagement by individuals to learn, hone, and further develop their capacities. Such activities are most likely to occur when individuals sense that this learning is important and see it as part of sustaining their sense of self. Table 3 sets out a range of these practices, with a description provided and those purposes associated with learning in and through work.

Table 3 Personal epistemological practices—premised on individuals' capacities, agency, intentionality, and sense of self.

Practice	Description	Purposes
Mimetic learning	Ability to imitate and interest to do so at work (Billett, 2014); a fundamental process of human learning (Jordan, 1989) by imitating implicitly or explicitly how experienced workers practice (Marchand, 2008), including asking questions or listening to them (Gardner, 2004)—a higher order activity.	Process through which goals, procedures (both specific and strategic), propositional links, and associations can be learned through personal engagement.
Ontogenetic ritualization	A system of communication and engagement between social partners negotiated through repeated social interactions (Tomasello, 2004); supports close guidance and reciprocal interactions in workplaces permitting co-workers to engage in learning reciprocally.	Basis through which to engage with others from whom guidance is derived.
Embodied knowledge	Ability to do rather than talk about it, arising through practice (Jordan, 1989); renders unconscious much of what is required for performance (Lakoff and Johnson, 1999; Reber, 1992).	Procedural learning derived through practice and rehearsal that becomes able to be applied without conscious recall.
Deliberate practice	Practicing skills and monitoring their improvement (Gardner, 2004) as the means by which agency, focused intentionality, and the act of rehearsal come together to secure effective performance (Anderson, 1982).	Process of rehearsing, honing skills, refining, monitoring personal performance, and making conscious efforts to improve performance.
Guided re-discovery	Novices engaging in situations where they can practice, hone skills, and gain experience by themselves, yet can still access direct guidance (Ingold, 2000; Makovichy, 2010).	Process of remaking knowledge through opportunities for observation, listening, and other forms of social engagement and practice.
Active engagement & construction	Importance of active engagement (observation, listening, and <i>mimesis</i>); apprenticeship means <i>apprehendere</i> in French (to seize, lay hold of, apprehend, and apprise with the mind—to inform, give form, to shape; Webb, 1999).	Learning arises through seeking out, actively constructing, and appropriating the knowledge able to be accessed.
Observation	Japanese word for apprentice is <i>minarai</i> —one who learns by observation; unobtrusive observation <i>minarai kyooiku</i> —serious learning progresses without didactic instruction (Singleton, 1989).	Provides access to goals, models for procedures, and bases for developing procedural capacities.
Averting gaze	Mediating the external (i.e. immediately social) contributions—actively ignoring erroneous suggestions to secure an immediate goal to effect productive activities (Glenberg et al., 1998).	Intentional engagement with what needs to be learned.
Readiness	The level and qualities of what individuals want to know and can do.	Mediates the capacities for learning as a result of earlier experiences (and learning).
Assent	Individuals' willingness to assent to effortful learning (Mishler, 2004).	Mediates how individuals engage with external suggestions, supports.

The kinds, breadth and diversity of these personal practices emphasize the centrality of the active engagement of individuals as learners. This includes the role that they play in initiating (Bauer et al., 2004), directing the intentionality (Malle et al., 2001) and focus of their thinking and acting (Rausch et al., 2017) associated with learning. Much of these practices are premised upon their existing knowledge and ways of knowing, based upon how they have reconciled earlier experiences (i.e. pre-mediate), which is quite central to understanding learning through and for work. Indeed, as with the learning of any other socially derived practice, it is insufficient simply to consider an educational experience, either organized in or through an educational institution or workplace setting. Instead, it is necessary to consider how people come to engage with that experience, which includes the kinds of societal sentiment which informs them whether such an activity is worthwhile and important.

From the above, it can be seen that understanding the processes of learning through work and enhancing those processes is likely premised upon three distinct sets of practices: (i) practice curriculum, (ii) practice pedagogies and (iii) individuals' personal practices, including what they know, can do and value.

Securing occupational capacities through practice

It has been proposed in this article that the growing interest in promoting learning through work, both for the initial development of occupational capacities and for sustaining and developing them further across working life, needs to be supported by understanding the particular ways how learning of occupational knowledge arises through work settings. Consequently, it is also important to identify and articulate the premises that assist in understanding and generating sets of concepts that can explain this phenomenon. These are essential in understanding and appraising workplaces as environments in schooled societies in which there is a privileging of learning processes and outcomes that arise through experiences in educational settings. The conceptual and explanatory elaborations advanced here offer bases to consider how the securing of occupational capacities can progress in contemporary times. Moreover, to achieve the outcomes which are now being sought by government, workplaces, workers, and educational institutions, it is necessary to advance ways in which these can be realized. Proposed here within the broad framework of a duality between workplace affordances and individual engagement are the key tenets of practice curriculum and pedagogies, and personal epistemologies. Listed above are a range of proposed models of practice curriculum that are, in different ways, applicable to specific kinds of workplaces and occupations. The listing of pedagogic practices has particular processes and purposes that they are likely to promote. And at least as important are the learners' personal epistemologies with their attendant processes and qualities. It is proposed that, together, these three elements help explain not only how learning through work can progress, but also the ways in which learning through work can be promoted to achieve the kinds of outcomes required for contemporary workplaces. Hopefully, these suggestions might assist with this important task.

Introduction

Archaeologists, urban planners, and designers are constantly examining connections between materials, the built environment and human behavior. Their respective fields have accumulated extensive bodies of theoretical, empirical, and practical work, with practitioners especially trained to reflect on the nature of human activity as it relates to culture and built forms. Conversely, in education, the influence of materiality in learning has gone largely unnoticed for many years. Traditionally, educators have focused on curriculum design, pedagogical practices and social interactions, while spaces, built forms, digital and material elements, are usually seen as a backdrop for where the “real” action happens—they have too often been neglected aspects of the complex learning entanglement in education (Carvalho and Yeoman, 2021).

This chapter explores the intersection between spaces, materials, culture and learning, and problematizes the need to look at past and present when designing for learning. The chapter suggests that paying attention to the qualities of materials, and the ways these might influence learning, is best considered within an ecology of elements—through searching part-whole relationships and noticing how multiple elements relate to one another and to learning activity (Carvalho and Yeoman, 2018). In other words, learning activity is seen as enmeshed in an assemblage of elements that includes physical spaces, artifacts, digital technologies, people, ideas, all coming together in a learning entanglement. Drawing on literature about a Māori *marae* in the context of Aotearoa New Zealand, the chapter makes a case for the materiality of a marae and its pedagogical function, as a space that reflects long-standing social values of positive interdependence and collaboration—values that have been around for thousands of years (Addis et al., 2011; Austin, 2011). The chapter argues that many of these long-standing values are being reframed, reformed, and reinstated in both material and digital incarnations (in learning entanglements), where their fundamental essence is still present and still influencing and shaping the ways students are being prepared for the future.

In addressing the present times, the chapter discusses how learning spaces have increased in complexity and are becoming more and more ubiquitous (Beetham and Sharpe, 2019). The chapter delves into the qualities of materials and learning spaces in modern society, discussing these in connection to the challenges of preparing our students for an evolving digitally mediated future, and therefore, the challenges associated with design for learning. Drawing on theories that foreground socio-materiality in learning (Fenwick, 2015; Sørensen, 2009) and networked learning (Goodyear et al., 2004; Networked Learning Editorial Collective, 2020), the chapter calls for a deeper understanding of the interplay between the physical (digital and material), conceptual, and social aspects of learning, and their combined influence on emergent activity.

Themes related to spaces, materials, culture and learning are explored as follows. First, the chapter brings a reflection about the materiality of a Māori marae, discussing its pedagogical function and the ways “learning,” “knowing” and “being” unfold in these spaces (Addis et al., 2011; Austin, 2011). Second, the chapter problematizes learning as part of a networked society, considering the role of material and digital elements, within learning ecologies in education (Carvalho and Yeoman, 2018, 2021; Damşa et al., 2019). The need to nurture skills connected to collaboration and critical participation in contemporary society is also foregrounded (Ananiadou and Claro, 2009; Sawyer, 2009). Third, the chapter discusses an architecturally inspired analytical framework that helps illuminate the structure of complex learning environments (Goodyear and Carvalho, 2014; Goodyear et al., 2021). And, finally, the chapter illustrates how ideas in this framework can be used to map relations between spaces, materials and learning within educational environments.

Overall, the chapter argues that materials matter, and that in order to best design for learning, educators need to notice the qualities of materials, while making sure these are not seen as isolated entities. Instead, it is important to account for multiple elements and to consider carefully how they influence the learning whole, searching for key designable components and understanding what

works well, and how. Only then, can we use this knowledge to (re)design our learning environments. As educators, it is important that we acknowledge and build on the past and present, if we are to figure out how best to prepare our students for an uncertain future.

Embracing the past—the materiality of a marae and its long-lasting values

Aotearoa New Zealand is a bi-cultural country in the south pacific, which recently reached a population of 5 million. History books tell us that when Captain Cook and his crew first arrived in 1769, Māori people had already been living in the land for nearly a thousand years (Austin, 2011). Over time, many other migrants also came to these shores. The 2018 census shows 70% of Aotearoa New Zealand population as European descendants, and 16% as Māori (Statistics New Zealand, 2020). Since the 1700s, there has been an increase in population diversity, Māori becoming a minority according to the census data. But even so, one could argue that the traditions of the Māori culture are still strongly infused in Aotearoa New Zealand society, in everyday living—deeply reflected on the nations’ identity, cuisine, language, and customs (Te Ara, 2020).

Māori studies have focused on social relations, art, culture and traditional knowledge, but some scholars have also specifically explored the architecture of Māori settlements and the interaction of Māori people with the built environment (Austin, 2011). Traditionally, Māori settlements were formed around a community building (or a meeting house) and its associated open space (the marae) (Austin, 2011). A marae therefore consists of “a cluster of buildings and spaces, usually incorporating a wharenui (meeting house), a marae ātea (an open space in front of the wharenui), a kitchen and dining area, and an amenities block” (Statistics New Zealand, 2014, p. 6). A marae may also include other spaces such as an urupā (cemetery). Over the years, as Māori migrated from rural areas to the cities, the phenomenon of an ‘urban marae’ also emerged, referring to their presence outside the context of the traditional tribal structures often in rural areas (Addis et al., 2011). Urban maraes provide a cultural space for Māori, particularly those who might have been distanced from their closest ones, after relocating to larger cities. These urban maraes allow for interaction with others who are perhaps experiencing a similar situation, so that people can connect, explore and understand their identity. Interestingly, maraes are not necessarily found only in connection to Māori in Aotearoa New Zealand, but there are also maraes throughout Polynesia in various forms (Addis et al., 2011).

A marae is essentially a space where a community gathers together for weddings, funerals, for community discussions and other social events. A marae belongs to a particular iwi (or a tribe), or to a whānau (family), and Māori see their marae as their place “to stand and belong” (Statistics New Zealand, 2014, p. 6). As such, maraes are places infused with symbolism and meaning, where the Māori community stands together but, at the same time, these are also physical spaces, with a meeting house, which has a specific architectural characteristic and layout, which often displays intricately ornated carvings, paintings and patterns (Fig. 1).

Māori traditions and knowledge have, for many years, been orally passed on via stories and songs, through many generations. As such, a marae plays a crucial role for the Māori community. Ka’ai (2008) refers to the symbolic cultural pedagogical significance of a marae, as an environment that allows teaching and learning and practice of traditional Māori pedagogies such as ako. Ako means both to teach and to learn—a single word that embodies learning as reciprocal, through the notion that knowledge and new understandings emerge through learning, but also through teaching (Macfarlane, 2015; Napan et al., 2020). In considering the pedagogical function of a marae, one positions learning activity as happening beyond schools or formal contexts, as occurring, for example, while one works alongside elders, and watches, observes and learns behaviors under their guidance (Addis et al., 2011). As a pedagogical tool, the marae is seen as an environment that nurtures positive interdependence and collaboration, helping to create a sense of whānau (or a sense of family), an environment where essential long-standing Māori values are passed on. These include core

Fig. 1 Meeting house at Te Whaiti. Original photographic prints and postcards from file print collection, Box 1. Ref: PAColl-5471-013. Alexander Turnbull Library, Wellington, New Zealand <http://www.records/22524369>.

cultural values such as having a sense of shared responsibility, learning to work with one another, showing commitment, nurturing positive interaction, connectedness, and solidarity (Addis et al., 2011).

As a community gathers together in a marae, they are encouraged to engage with particular ways of learning, knowing and being, where elders might tell stories and sing songs and, as the younger generation experiences these traditions, they do so, within a particular physical setting. This physical setting also arguably plays a significant role in the passing on of Māori traditions. As Addis et al. (2011) explain, the communal large space and the intricate architectural features of a meeting house—represented through carvings and paintings that decorate the space—are often used as mnemonic aids, helping the younger and old to memorize genealogies and the values of the culture. Surface patterns and paintings function as references, and through touch and sight might help people capture and share their stories (Fig. 2). A marae meeting house reflects an atmosphere that seems created to nurture cultural values, where the types of interaction give shape to a type of “pedagogy” infused with a mission of passing on the traditions of a culture. But the patterns, carvings and decorations themselves are also symbolically holding pieces of Māori stories. Features in the walls and ceilings act as reminders to those who are listening and to those who are telling these stories.

In thinking about a marae and the types of activities that unfold in these spaces, a beautiful example emerges to illustrate the power of the performativity of material things—where materials and the surroundings subtly suggest specific types of interaction and learning. A socio-materialist stance often challenges us to move away from an isolated focus on either entities or individuals, toward a more nuanced understanding of material relationality in learning (Fenwick and Edwards, 2011, 2014; Gourlay and Oliver, 2018; Sørensen, 2009). Socio-materialism speaks of knowledge, people, objects and systems, as influenced by connections and activity, a perspective where performativity comes into action through complex webs of relations. As Fenwick (2015) stresses, things “act together with other types of things and forces to exclude, invite, and regulate particular forms of participation” (p. 670). And it is easy to imagine a marae subtly inviting specific forms of participation: the open plan of a meeting house “speaks” of gathering together in a community hall, the carving and paintings “support” the oral stories, helping the passing of the traditions and values of this culture.

The essence of Māori values such as the shared responsibility, working with one another, commitment, positive interaction, connectedness, and solidarity (Addis et al., 2011), can also be seen as infused broadly in Aotearoa New Zealand’s education system. From 2015 onwards, Aotearoa New Zealand’s policies, standards and guidelines (Benade, 2017; Education Review Office, 2018; New Zealand Ministry of Education, 2015) started to reflect global trends in education, which encouraged schools and universities to transition into new spatial configurations, or into flexible learning spaces (Cardellino et al., 2017; Daniels et al., 2018; Wood, 2019; Woolner et al., 2018). As such, schools and university spaces have been (re)designed not only to accommodate technology-rich activity, but also to enable collaborative teaching and learning in ways that actively engage students in scaffolded inquiry (Mulcahy et al., 2015). Te Kete Ipurangi (2020), an educational portal created by the New Zealand Ministry of Education, suggests that working in an innovative environment involves considerations about the physical, social, and pedagogical aspects of learning. These types of environment support strengths-based teaching and learning and promote flexibility, agency, ubiquity, and connectedness. In these environments “reflections and inquiries are shared, and communities engaged [which often] leads to a more robust, continuously improving community of practice” (Te Kete Ipurangi, 2020, online). These views of an innovative learning environment seem connected to positive interdependence and collaboration, and often acknowledge that navigating these changes from traditional to flexible spaces in formal education settings requires experimentation, adaptation and deep consideration about what is valued and what is possible in newly configured spaces. Te Kete Ipurangi (2020) refers to the role of emerging technologies and the development of teaching practices that support team teaching and collaboration. Similar emphasis on *connections* is also reflected through the notion of networked learning, a field of study that examines the use of technology in the context of learning and as a tool to connect to others, to learning resources and to a learning community (Goodyear et al., 2004).

Embracing the present—shaping spaces for networked learning in contemporary societies

A recent definition of networked learning explains that:

Networked learning involves processes of collaborative, co-operative and collective inquiry, knowledge-creation and knowledgeable action, underpinned by trusting relationships, motivated by a sense of shared challenge and enabled by convivial technologies. Networked learning promotes connections: between people, between sites of learning and action, between ideas, resources and solutions, across time, space and media.

Networked Learning Editorial Collective (2020, p. 8).

Indeed, people are living in increasingly connected societies. Some may use the term *connections* to refer to the wider access to digital technologies or the ability to communicate to one another in an instant (Dohn, 2018). There is no doubt, it is now possible to experience simultaneously multiple places and situations (Gourlay and Oliver, 2018), like being in a café in New York while chatting to a friend in Bangladesh, or watching a teleconference seminar presentation broadcast in London, while stroking a cat in your home lounge in Sydney. But the term *connections* can also be used to reflect how what happens to one of us at one side of the world, often reverberates elsewhere through a chain of interdependent links, and in a range of situations. Essentially, no matter where one is in this world, there are common issues that affect all of us as global citizens. Famine, global warming, the displacement of refugees, human rights violation and recently the COVID-19 pandemic are just some examples. When young people participated in protests led by climate activist Greta Thunberg (2019), they did so to raise collective awareness of the need to take action as a community and engage with climate issues in a more proactive way. The pandemic arrived and reminded us again about the need to think as a community, the need to look after one another, if we are to eliminate this threatening virus. These are highly complex global issues and, arguably, would be best approached if people from different disciplinary areas worked co-operatively, jointly searching for effective responses. Often called “wicked problems”—these are problems that are ill-defined, for which there is more than one possible explanation and for which there might be multiple potential solutions (Buchanan, 1992). They demand that people work with one another, sharing ideas, exchanging expertise, and it is in trying to reach a shared understanding of the issue at hand, that collective action can successfully take shape, allowing society to move forward.

Now more than ever educators need to look beyond preparing students for future employability only, and instead help students develop the capabilities so desperately needed, so that they can contribute to the shaping of sustainable ways of living. Educators need to support young people to be empowered, to feel that they can work together to create and build a better world for all of us.

A core challenge for educators is indeed how to create spaces for learning in ways that support young people to learn how to collaborate, how to think creatively and critically, how to facilitate students’ engagement with problem-solving activity or how to help young people engage with the use of technology in productive ways (Ananiadou and Claro, 2009; Sawyer, 2009). As educators we need to make sure young people are harnessing the potential or the positive side of technologies, while also still being mindful about its constraints and wary of the unethical uses of digital data (Pangrazio and Selwyn, 2019). Educators need to shape spaces for learning in ways that will successfully support students to feel connected, to feel that they can productively work with one another, to encourage their curiosity and experimentation, to foster their creativity and critical thinking. In sum, this is essentially an educational design problem, and more specifically, a “wicked problem.”

The Organization for Economic Co-operation and Development (OECD) started exploring innovative ways of encouraging young people’s learning through the Innovative Learning Environments (ILE) project (OECD, 2013, 2015a,b). Their main focus was on generating forward-thinking insights that would help devise productive guiding principles to support learning and innovation in the new millennium (Blackmore et al., 2012). The project emphasized learner-centered approaches to education, looking at how teachers might support inquiry and autonomous learning while acknowledging individual and group differences. Social aspects of learning, involving cooperation and group arrangements, were also highlighted. More recently, the OECD’s Learning Environments Evaluation Program (LEEP) (OECD, 2017, 2019) further developed ideas connected to learning environments, which were then described as “the result of interactions between physical resources (i.e., learning spaces, material and technology), learners, educators, content, learning leadership, society and policy” (OECD, 2017, p. 12). It is interesting to notice that in this definition a learning environment is seen as influenced by multiple elements, with a special reference to “learning spaces, material and technology”. In so doing, LEEP re-positions the significance of material and digital elements in learning, bringing these to the fore. Such a perspective is also in line with developments in learning theories and ecological approaches which see learning activity as part of an ecosystem of multiple elements (e.g., learners, educators, families, communities, knowledge, digital and material resources) (Barron, 2006; Damşa et al., 2019; Ellis and Goodyear, 2018; Vartiainen et al., 2018). Not surprisingly, the OECD policy developments have also been influencing multi-million dollar investments in (re)building new infra-structure, at schools and universities across the globe, and these policies also recognize the need to address learning in a digital world.

As such, learning spaces in schools and universities have been transitioning into new configurations, which often include open plan layouts, with bright flexible furnishings that are light and easily moveable, for example with desks that have wheels. In addition, these spaces are often set to accommodate multiple digital devices in use. The flexibility of the materials and furnishings allows teachers and students to quickly reconfigure the space according to the type of tasks students are asked to engage with. Activity in these newly designed spaces is rarely homogenous, as students might be constantly switching between periods of individual reflection, to a group work activity, they might be watching a one-to-many presentation, or the broadcasting of a video, or they might be using digital devices either individually or in groups, while completing a collaborative task and so on. These open spaces also

require that teachers work with others, exchanging ideas and developing collaborative skills (Carvalho, 2021; Carvalho et al., 2020). Not only are they preparing our students for learning how to collaborate and tackle the complex problems of our societies, but teachers also need to engage in collaborative problem solving themselves. And within a school or university setting, collaborative activity often involves people's ability to navigate mental, social, and spatial interactions. People need to learn how to negotiate shared meaning and so, to be successful in these types of situations, they need to understand how best to orchestrate tools and materials available to them, but also how to employ social strategies that might help sustain their (learning) activity until a resolution is reached.

As the complexity of learning situations around us increases, and with more demands for collaboration and participation, educators are having to rethink their pedagogical strategies, but also to (re)consider in depth how to design for learning in a digital era (Beetham and Sharpe, 2019).

The next section introduces an approach used to frame the analysis and design of complex learning environments.

Framing the analysis of complex learning environments

The Activity-Centered Analysis and Design (ACAD) framework (Goodyear and Carvalho, 2014; Goodyear et al., 2021) is an analytical tool that builds on ideas from architecture and design, to foreground the structural elements that come together in a learning network. The framework is concerned with educational design, and it acknowledges the need to consider the complexity of the diverse assemblages of tools, tasks and people, as one engages in orchestrating and navigating knowledgeable action in contemporary society.

ACAD allows educational researchers to break down the complexity of learning situations and, in so doing, to consider relationships between designable forms and emergent learning activity. In placing activity at the center (Fig. 3), ACAD expresses that what learners actually do is of utmost importance—their actions, thoughts and feelings. Learning outcomes are only indirectly reached, as learners have agency to co-create whatever is designed and proposed by a teacher. As such, the framework lays out three main “designable” components and a fourth element that is characterized as “emergent”. The three designable structures are:

- *set design*—includes digital and material tools or resources which are made available to learners at a learning situation (e.g., a pen and paper, a smartphone, a special configuration of furniture in a room);
- *social design*—this is about the types of social arrangements of learners, which can include scripted roles or divisions of labor (e.g., working in pairs or groups) and
- *epistemic design*—proposed tasks, ways of knowing (e.g., what are learners asked to do, pacing and sequencing of information).

Fig. 3 ACAD framework. Adapted from Goodyear and Carvalho (2014, p. 59).

The fourth element in the framework is the *co-creation and co-configuration activity*, which is characterized as emergent and not designable. This element relates to learners' agency to re-configure and co-create what has been proposed by a teacher. Underlying the ACAD framework is a view of learning that considers learners' activity as epistemically, socially and physically situated (Goodyear et al., 2021). It is the set design dimension that most acutely brings the material and digital elements to the fore but, as the framework highlights, elements should be seen as part of an assemblage. One may consider what it means to use a certain material or to have access to flexible furniture, particularities of the layout of a space and how it accommodates the use of technologies, but it is also important to consider connections to social and epistemic elements. The ACAD framework emphasizes learning activity as an emergent phenomenon, which is influenced and shaped by various design elements, which can be noted at the micro, meso and macro levels (Carvalho and Yeoman, 2018; Goodyear et al., 2021).

Applying the ACAD lens to micro, meso and macro levels

In reflecting on the question “*how do we shape our spaces for learning?*” different perspectives and levels of granularity might be considered. For example, one might look at this very question while focusing on micro, meso and/or macro levels (Carvalho and Yeoman, 2018). To illustrate how the ACAD lenses may support the analysis of part-whole relationships at these different levels, the chapter now presents two scenarios. The first scenario explores the structural dimensions based on the earlier description of a Māori marae, in relation to designable components and the types of activities that unfold within the space of a meeting house. The second illustration foregrounds the application of the ACAD lenses in relation to innovative learning environments in schools and universities.

ACAD and a Māori marae

In the Māori marae example, at the *micro level* of *set design*, one could highlight elements such as the carvings in the walls and the meeting house open space itself. This is a space where the community gathers to share stories or responsibilities. The opportunities for young and old people being together can be seen as part of *micro social design*. The young generations watch and observe elders to learn about specific knowledge or cultural stories, or to learn how to share responsibilities, at the *micro epistemic design*.

At the *meso-epistemic design*, there are the traditional Māori pedagogies, such as *ako*, or principles such as positive interdependence. *Meso-social design* would include arrangements such as being from a particular *iwi* (or tribe) or *whanau* (family) and *meso set design* could signal the wider setting of the Māori marae. At the *macro-set design*, one could refer to the geographical location of Aotearoa New Zealand as a Pacific Island, as a bi-cultural nation (*macro-social design*), where long standing Māori values (*macro-epistemic design*) are all connected to the types of activities that unfold within these settings (Table 1).

ACAD and innovative or learning environments

Similarly, ACAD can be used to illuminate core design components in educational research or when undertaking educational design work to shape spaces for learning. Again, there are different perspectives and levels of granularity that might be considered (Table 2). At the macro level of educational design, one might focus on the development of government policies, or on specific learning theories and best practices (*macro-epistemic design*). It might involve considerations about the built environment and core infrastructure, including access to the Internet, bandwidth and WIFI. This is about whether the appropriate infrastructure exists or not, or what provisions are needed to be in place for our learners, so that some are not missing out on access to core resources (*macro-set design*).

At the meso level, one might consider particularities of an educational institution, looking at what might be the university or school's educational mission, how their strategies relate to learning, how curriculum is organized or how courses relate to one another (*meso-epistemic design*). It might involve noticing what types of learning spaces are available and how space is allocated and occupied by educators and students in a given institution (*meso-set design*). And at the micro level, we might consider the shape of spaces for learning while looking at more specific and local issues at the classroom level. We might notice the tools that are brought to our learners, or what students are working with, the digital and material resources that students might have access to, or how furniture is going to be (re)arranged in the space (*micro-set design*). We might look at specifics of learning tasks, their sequencing and pacing, or what students are asked to do (*micro-epistemic design*). Importantly, however, these scale levels are

Table 1 Māori marae mapped through the ACAD dimensions.

	<i>Set</i>	<i>Social</i>	<i>Epistemic</i>
Macro	Aotearoa New Zealand	A bi-cultural nation	Long standing Māori values
Meso	Marae	A <i>iwi</i> (or a tribe), or a <i>whanau</i> (family)	Traditional Māori pedagogies Ako (reciprocity in teaching and learning)
Micro	Meeting house, carvings in the walls	Elders, adults and children coming together	Opportunities to share stories, share responsibilities, watch, observe behaviors under elder's guidance

Table 2 Innovative learning environments and the ACAD dimensions.

	<i>Set</i>	<i>Social</i>	<i>Epistemic</i>
Macro	Wider infra-structure WiFi, access to Internet	Social and political structures	OECD policy Government policies Government curriculum Standards and best practices
Meso	Allocation of space in a school	Community orientation School culture	School vision and mission Discipline curriculum
Micro	Open plan classroom flexible spaces Breakout rooms Light furniture Digital devices	Students working in groups Specific scripted roles	A learning task involving creating a knowledge artifact (e.g., a video about the habits of an animal of interest)

also often interconnected. For example, policy (macro) is likely to influence an institution's mission and curricula (meso), and without the appropriate technological infrastructure (macro), it may be difficult to use a laptop in a lesson (micro) and so on.

An awareness of these connections is also important for educational research even when a researcher's interest might be on specific learning processes. For example, as a researcher explores students' engagement in a classroom activity, the focus may be at the micro level. The researcher is perhaps capturing students' interactions, or interactions between teachers and students, but emergent activity can also be seen in relation to other multiple structural components. It may include aspects related to the task itself and what students are being asked to do (*micro epistemic design*); how are students organized, whether they are working individually or in groups (*micro social design*); and how is the learning setting organized, what tools and resources are being used, what devices students are working on (*micro-set design*). All these elements are likely to influence what students actually do in the learning activity. And again, what happens at the micro level is influenced by meso and macro structures. For example, a classroom task that involves a group of students searching the Internet about a given topic, will only work if students have access to devices and to a wider infrastructure, such as WiFi or satellite reception. The particular task that a teacher designs for her students, takes into account a discipline curriculum (*meso epistemic design*), which in turn might be based on government policies, OECD standards and best practices in education (*macro epistemic design*). As an ecological approach, the ACAD framework may help educators break down the complexity of learning environments, to render visible the connections between multiple key designable elements in set, social and epistemic design, at different levels of granularity (micro, meso and macro), which are all important when considering learning activity in innovative learning environments.

Conclusion

In many parts of the world, conventional teaching models are evolving in accordance with new developments in the learning sciences, but also through a more marked presence of emerging technologies in classrooms, overall requiring that formal learning environments are upgraded to reflect 21st-century practices (Deppeler et al., 2021; Freeman et al., 2017). These open and flexible learning spaces have been on the rise in schools in Australia (Yeoman, 2016), Aotearoa New Zealand (Benade, 2017; Fletcher and Everatt, 2021), in the UK (Daniels et al., 2018; Woolner et al., 2018), in Finland (Niemi, 2020; Kokko and Hirsto, 2020), the Netherlands (Könings et al., 2017), Austria (Schabmann et al., 2016), and many other places. As such, researchers, educators, government and policymakers worldwide are trying to figure out what valuable elements should be included as part of contemporary design for learning, in order to best support processes of educational transformation.

Learning theorists have been calling for more holistic ways of seeing learning, or for considering learning activity as part of larger ecologies. Ecological perspectives are usually grounded on sociocultural and socio-material approaches to learning. They portray the mutually constitutive relations between individuals and larger educational and societal contexts, as also influencing learning processes. Hutchins (2010, 2014) offers a systemic perspective, where cognitive phenomena are not seen as individualized or isolated, but instead, as emerging through distributed activity. And according to Barron (2006) a learning context often involves "a unique configuration of activities, material resources, relationships, and the interactions that emerge from them" (p. 195). Vartiainen et al. (2018) refer to learning networks as co-evolving and connected to multiple contexts, social practices and tools. Essentially, while it is crucial to recognize the role of materials in learning, materials and spaces themselves cannot be seen in isolation. As Woolner (2010) reminds us, although a learning space might help or hinder particular ways of using materials, or invite some forms of social interactions, the space itself does not determine the teaching and learning that takes place there. A more holistic way of understanding the influence of tools, tasks and people on learning activity is needed, one that includes sensitivity to the materials (Ingold, 2013).

As the chapter illustrates, ecological perspectives are also reflected in international policy developments related to innovative learning environments, seen as involving learners, teachers, the community, pedagogical practices, and tools and resources (OECD, 2013; 2015a,b, 2017). Across the globe, as teachers and students transition into open and flexible learning spaces, educationalists are pondering what is needed when embracing new practices, for example as teachers learn how to find optimal ways of

working in teams, or how to prepare their students for more sustainable ways of living. Indeed, educators have reported experiences that involve having to learn to team teach and collaborate, having to adapt, and being in a period of transition, which is ongoing and evolving (Carvalho, 2021; Carvalho et al., 2020). However, as the chapter reveals, some of the values enacted within these innovative learning environments do not appear entirely new, and instead seem nicely related to the long-standing values of Māori traditions—namely the importance of nurturing positive interdependence, learning to work together with one another, learning how to collaborate, feeling connected and respected by others (Addis et al., 2011). One could perhaps argue that some of these educational practices are not new but, instead, education systems are somewhat reframing and reforming some of these long-standing values, trying to figure out how these can be reinstated within contemporary innovative learning environments, where material and digital are also to be considered as important aspects of the complex learning entanglement. Transition into new flexible configurations may require honoring valuable past experiences, as well as considering current contemporary needs, so that learning environments can support what we value in learning going forward, in evolving networked societies.

One of the most vexing but also most important research questions in the intersection of education and psychology is whether there are gender differences in intelligence and learning. For the answers to this question has important, nay, even profound implications for how we educate boys and girls. Do boys and girls have different purported “learning styles,” and are we doing either gender a disservice by presenting the material the same way, in the same classes, with co-educational schooling? Some readers will likely have firmly entrenched views on the subject; others may be undecided but curious to know more. Often the subjective impressions we draw from our own teaching experiences can differ from those of other educators, and the field of education is a broad profession that accepts many diverse perspectives on teaching. Endorsement of support for single-sex schooling is also guided by our political and ideological worldview: both educators and parents are more likely to believe single-sex schooling is beneficial if they hold less liberal, more conservative outlooks. Indeed, writes Mills (2004), single-sex schooling is explicitly marketed to that demographic and often accompanied by an appeal to traditional gender norms. Regardless though of which camp you may fall under or, if indeed, like many educators you remain undecided, the founding tenet on which single-sex schooling rests is that boys and girls think, behave, and learn differently to one other.

Such claims should be put to the test, and there is a large body of scientific and educational literature that does just that. There are many myths and misconceptions amongst educators and parents about the nature of gender differences in intelligence; these gender stereotypes can serve to undermine student performance and magnify gender gaps in learning outcomes. Beliefs that there is a “smarter sex” are often propagated in educational literature or that males and females are radically different (aka the “men are from mars, women from venus” perspective), as well as in popular culture. However, neuroscientific evidence is unequivocal that males and females are equal in general intelligence, and that there are also gender-specific differences for more applied cognitive abilities. The purpose of this chapter is to examine how gender affects learning outcomes. Firstly, it examines gender differences in verbal and language abilities, where females typically outperform males. Secondly, it examines gender differences in quantitative reasoning (mathematics and science). In this domain the picture is less clear, as students in Western countries perform quite differently to those in other cultures.

Rather than cherry-picking certain studies to present an argument in support or against the existence of gender differences, this review examines evidence from large-sized nationally representative samples to determine whether there are different patterns of educational achievement between males and females. This represents the gold standard of evidence for examining gender differences (Becker and Hedges, 1988), as most studies recruit highly-selective and non-representative samples to estimate the extent (if any) of gender differences. Selection bias is a serious problem in educational and psychological research, as we know that there are important demographic factors that also impact educational outcomes and interact with gender. Older reviews on this subject have presented highly selective evidence which may lead to erroneous conclusions about gender and mathematics (for a critique see Spelke, 2005), or verbal ability (Wallentin, 2009). A further limitation of much of the literature is that it is highly US-centric, and ignores gender and learning in an international context. As the reader will see, there is considerable variation cross-culturally. This

suggests that sociocultural factors and educational systems contribute to the presence or absence of gender differences. Gender differences in some learning outcomes are quite large and impactful, while in other areas are relatively small. Educational implications are then discussed.

Gender differences in intelligence

Psychology is the discipline that studies human thought and cognition, and one of its aims is the accurate measurement of human intelligence. Historically, the fields of education and psychology have always been intertwined. Indeed, the very first intelligence tests used in psychology were developed by Alfred Binet under the commission of the French Ministry of Education, to devise objective procedures for measuring student aptitude and classroom placements. From this, sprang forth the intelligence and educational assessment movement; prior to this, decisions made about intellectual aptitude and educational abilities of an individual relied, instead, on subjective impressions, racial/gender stereotypes, and often socioeconomic class. More than a century later, after the measurement of millions of children and adults, we have a firm bedrock of data to answer the question of whether there are actually gender differences in intelligence, and if so, how large is their magnitude. The answers are more nuanced than is commonly assumed, and depends on both how and where one looks.

From the outset, let the reader be clear in their mind that there are no gender differences in general intelligence (IQ). When representative samples of men and women are compared at the population level, their psychometrically assessed general intelligence is equivalent (Jensen, 1998; Neisser et al., 1996). There is near-unanimous consensus in psychology and neuroscience that men are just as smart as women (or conversely, women are just as smart as men!). Sternberg (2014, p. 178) concluded that “there is no evidence, overall, of sex differences in levels of intelligence.” However, a large number of studies have documented that the performance of males shows greater statistical variance than females (i.e., there are a greater number of both high-scoring and low-scoring males at the extreme tails of the ability distribution), termed the great male variability (GMV) hypothesis. For the non-mathematician, the practical effect of this is that even though there are no gender differences in overall IQ, recruiting from highly select samples that are high in ability (such as groups of gifted and talented) may result in a greater number of high-achieving males, while selecting from a lower ability sample may see boys and men overrepresented with learning difficulties. This can lead to a distorted impression sometimes among educators working with such populations: either that boys are “smarter” than girls if they work with gifted and talented, or that boys are “less capable” by educators dealing primarily with remedial students.

Subjective impressions of gender differences in intelligence are also affected by the books and literature that parents, educators, and policy-makers read. There is no shortage of authors arguing there are large biological differences between males and female brains (Elliot, 2009), who talk about the effect of “raging hormones” on learning, or rely on fallacies around gender differences in brain size and intelligence (Lynn, 1994). These neuromythologies largely ignore peer-reviewed scientific evidence, and reflect, to a large degree, implicit beliefs about human intelligence and gender (Halpern, 2010). When asked, most adults will agree that men and women are equal in intelligence but when researchers ask large representative samples to estimate their children’s intelligence, both mothers and fathers rate the intelligence of sons as being higher than daughters (Furnham et al., 2002). Despite there being no gender difference in objectively measured IQ, when asked to provide an estimate of their own intelligence, men on average rate their intelligence as higher than do women (Rammstedt and Rammesayer, 2002). This finding is robust and has been reproduced cross-culturally (Szymanowicz and Furnham, 2011), and has been termed the male-hubris/female humility effect (Furnham et al., 2001). So it seems we have an innate predisposition to believe quasi-scientific arguments that since men’s heads and brains are slightly larger than females, males might just possibly be brighter and more capable than females,¹ particularly if they suit our ideological worldview or implicit beliefs about gender (Nosek et al., 2002). This is why it is important to consider evidence on gender and intelligence carefully: as Carl Sagan so elegantly quipped, extraordinary claims require extraordinary evidence. We should hold literature on gender and learning to the same standard.

Gender differences in specific cognitive abilities

While it is true that, overall, men and women are equally intelligent, we do also see gender-specific patterns for certain types of cognitive tasks (i.e., that some types of tasks show a female advantage and others a pattern of higher male performance). For example, it may come as no great surprise to educators that there is a female advantage in certain verbal and language tasks—the most common of which encountered in educational settings is reading skills (Logan and Johnston, 2009). Boys and men, as a group, tend to show greater performance for visual-spatial tasks such as mental rotation or navigation (Voyer et al., 1995). Visual-spatial reasoning also lays down a foundation for quantitative reasoning (mathematical and scientific aptitude). Males do show slightly higher mean scores on standardized tests of mathematics and science achievement (Reilly et al., 2015), but the extent of this is not nearly as large as the gender gap in reading. This may contribute to the underrepresentation of women in certain fields of science, technology, engineering and mathematics (STEM). But we should also be mindful that when psychologists make such

¹This argument plays on the neuroscientific fallacy that there is a linear correlation between brain volume and intelligence. As I jokingly remind my students when teaching about intelligence, following this line of reasoning the elephant must have a vastly superior intellect to us all!

statements, we are talking about group differences at the population level: some males score extremely high on reading and language tasks just as some females score low on them. A child's gender, in and of itself, should never be used as a proxy for measuring ability when making decisions about educational placements, just as an applicant's gender should not determine their suitability for job-hiring.

The three domains outlined above (verbal and language abilities, visual-spatial ability, and quantitative reasoning) are the most clearly identified and actively researched areas where we may see gender differences in cognitive abilities. There are other areas such as moral reasoning (You et al., 2011), nonverbal perception (Hall, 2005), and emotional intelligence (Petrides and Furnham, 2000) which are more contentious, but as they also involve non-cognitive processes (e.g., social and emotional) they are somewhat impure and not strictly "cognitive" abilities. Furthermore, on many—perhaps even most—cognitive tasks, males and females show similar levels of performance. So, it is important when reading the literature to keep this in perspective: there are gender differences for certain types of cognitive tasks that may impact learning, but for most types of reasoning males and females as a group show equal performance.

Out of the three domains, verbal and language abilities have the most impact on educational achievement, however, the gender gap in visual-spatial ability contributes to later gender gaps in mathematics and science. Therefore, one must be careful not to make too much of gender differences in cognition ("males and females are worlds apart"), but neither should one make too little of its educational impact either—particularly in the case of verbal and language abilities which scaffold educational achievement in secondary and tertiary education. In some areas, there are important effects of gender on learning that lead to later inequality of outcomes (Riegle-Crumb et al., 2018; Buchmann et al., 2008). For example, across most Western nations, more women than men enroll in college/university education after leaving high school, and when they do, women have quite a higher completion rate (OECD, 2020). A growing number of educators have expressed concern that gender gaps in literacy are leaving a generation of young men unprepared for future learning (Buchmann et al., 2008). We also live in a time of technological disruption, when traditionally male-dominated professions (e.g., manufacturing, assembly, transport) face the risk of automation and elimination of the need for unskilled or lowly-skilled labor (Muro et al., 2019). The ability to read and learn new skills will be vital to prepare students for the future. We also see gender inequality in the other direction, with a strong underrepresentation of women in many fields of science, technology, engineering and mathematics (STEM). While progress has been made in some fields of science (particularly biology and life sciences), women remain greatly underrepresented in most others (National Science Foundation, 2019). High-tech professions have also been more resilient against disruption during the COVID-19 pandemic, and STEM careers offer greater economic security—boosting female representation could make much-needed progress in addressing the gender-wage gap. Even small differences in equality of educational outcomes at the population level translate to large economic ones, making it important for all educators to understand how gender may affect learning.

Interpreting the magnitude of gender gaps

A difficulty most non-psychologists and statisticians encounter when reading literature in this area is how to evaluate the magnitude of gender gaps (i.e., just how large is the difference between the typical male and female student, and whether we are making headway in addressing these gaps). Most studies in psychology and the social sciences describe evidence in terms of "statistical significance." Statistical significance is a way of evaluating the likelihood that a difference observed between two groups (such as boys and girls) is genuine and not illusory. It indicates whether or not if we were to repeat the assessment with a different group of randomly selected students, we would likely see the same results. We use the probability value, also known as the p -value, or sometimes even just referred to as p (italicized). It is a statistical safeguard that the evidence is solid—but the term statistically significant often gets truncated to "significant," which has a very different meaning in everyday language. It also privileges studies with larger sample sizes: gather a sufficiently large enough sample and even a very small difference in means may be statistically significant, even though the magnitude of the gender gap may be trivial in size. As I often remind my statistical students, it is not the size of your p that is impressive! Rather, you should be evaluating the magnitude of the difference between two groups, using a metric like an effect size. This practice allows the reader to evaluate whether a gender gap is *practically* significant instead of merely statistically significant.

Effect sizes provide a quantitative (i.e., numerical) index of relationships between variables like gender. These provide an objective way of describing the magnitude of an observed effect in a way that non-statisticians can evaluate without formal training (for a gentle introduction to the topic, see Hedges, 2008). We use them to communicate the strength of an observed difference in a format that will be accessible to anyone: from educators to parents to policy-makers. The difference between two groups, such as boys and girls, can be expressed as Cohen's d . Understanding the statistical formula behind it is not necessary, but for the genuinely curious, it is the difference between two means divided by their pooled standard deviation which expresses it in standardized units. By convention, a positive effect size ($d > 0$) indicates higher male performance while a negative effect size ($d < 0$) indicates higher female performance.

Cohen (1988) offered some initial guidelines for interpreting effect sizes, applying the following labels to guide interpretation: $d = 0.20$ would be regarded as a relatively small difference between groups, while around $d = 0.50$ or so could be regarded as medium and $d = 0.80$ as large. Most effects studied in the social sciences and education are "small," with some medium and very few being large. These labels were intended as a starting point for a non-statistician to use, but Cohen also advised interpreting effect sizes relative to other (known) effects. For example, when a study reports a gender gap in reading as being "small," by Cohen's (1988) guidelines, we might also compare it to the gender gap in mathematics so as to allow for a comparative interpretation. By

way of example, two separate studies examined gender differences in large-scale national assessments of American school students in reading and mathematics. For reading, Reilly et al. (2019) report an effect size of $d = -0.32$ for students in the 12th grade which would be regarded as “small to medium” under Cohen’s guidelines, but is actually three times the size of the gender gap found in mathematics, $d = 0.10$ (Reilly et al., 2015). It is often helpful then to relate the size of gender differences in one area to another. So while “small” and “medium” might be useful yardsticks to go by, the reader is reminded that these were small only in a statistical sense, and that even small mean differences have profound educational and occupational implications for those students affected. Such differences also affect a student’s attitude towards reading, mathematics and science, as well as self-efficacy beliefs; gender gaps in these domains are typically far larger than actual abilities.

Gender differences in verbal and language abilities

Verbal and language abilities is a term that encompasses any task involving words and language, covering both *language reception* (listening and reading) as well as *language production* (orally or in a written form). In what was for its time the first truly comprehensive review of the psychological and educational literature on gender differences, Maccoby and Jacklin (1974, p. 351) concluded that “girls score higher on tasks involving both receptive and productive language, and on ‘high-level’ verbal tasks (analogies, comprehension of difficult written material, creative writing) as well as upon the ‘lower-level’ measures (fluency).” This view is supported by more contemporary researchers, with a female advantage seen in verbal fluency, spelling, grammar, reading and writing, and oral comprehension. Indeed, the only area of language where we do not see a pronounced female advantage is in word vocabulary: for most students, vocabulary is linked to the amount and variety of reading a student engages in as well as their general intellectual ability. But on all other tasks, there appears to be a pronounced female advantage though the magnitude of this gender gap varies across the type of task.

Reading

In an educational setting, the most prominently tested language skill will be reading ability. There is an emphasis on phonetic skill and whole-word reading at earlier grades, but as a child progresses through successive years of schooling, emphasis is placed less on the mechanics of reading and more on the speed of reading and quality of reading comprehension. Thus, the skills being assessed in early years are more remedial, while educational assessments in high school focus not just on basic reading skills but also reading comprehension and understanding. Large-scale educational assessments of reading achievement typically measure both students’ overall reading ability and whether they reach a minimum literacy benchmark. While boys are already greatly overrepresented in the number of children formally diagnosed with reading impairment or dyslexia (Berninger et al., 2008), there is a greater number still that fall at or somewhat above the clinical threshold for a formal diagnosis (Shaywitz et al., 1992). While educators will already be familiar with a higher number of boys than girls being classified as dyslexic, what sometimes comes as a surprise is that there are also mean gender differences in reading (i.e., the typical boy scores much lower than the typical girl).

Poor readers find themselves at a profound educational disadvantage compared to their peers. Not only may they struggle with reading tasks, but there are flow-on effects to other domains of learning given the amount of independent reading expected of students in high school. Reading ability is also correlated with reading interest and motivation. When reading flows easily for a student, it becomes an easy (or at least achievable) task, while it may be effortful and fatiguing for a poorer reader. We also know that the amount of time devoted to reading is also associated with reading improvements. Students with a higher starting point tend to receive greater practice over time, while poor readers tend to read much less than their peers (Harmon et al., 2016). For this very reason, early reading intervention is widely acknowledged by educators as critical (Foorman et al., 1997), and is typically offered to those identified as very poor readers. The long-term outcomes for students receiving early intervention are some degree of improvement (Hurry and Sylva, 2007), though they may still qualify for a diagnosis of dyslexia later in life. However, a considerable number of students still struggle with reading but at a sub-clinical level that prevents them from qualifying for diagnosis and intervention. This, in turn, holds back language development and acquisition of new learning in other domains; children who are functionally literate but who struggle to read and comprehend a textbook are then ill-equipped for high school and college. The distribution of sub-clinical poor readers appears to fall along gendered lines, but concerted efforts have been made in recent years to try to address this with often innovative suggestions. An important research question remains whether these efforts are actually productive, and whether educators are making headway over time.

Such answers may be determined by examining data from large, nationally representative samples of educational achievement that track student performance over a lengthy timeframe. For students in the United States, the National Assessment of Educational Progress (NAEP) has evaluated student progress in reading for over three decades using a national reading framework. It makes for one of the largest available datasets tracking reading over time, but until recently had seen little secondary analysis beyond annual reports noting statistical significance. Reilly et al. (2019) examined data from over 3.9 million students from the period 1988 to 2015. Due to the large sample size, all assessment waves were statistically significant, but the study also evaluated the magnitude of the gender gap averaged across all assessments. There were relatively small gender differences observed for students in Grade 4 ($d = -0.19$), but these grow progressively larger with additional years of schooling. By eighth grade, the gap between boys and girls has grown to small-to-medium in magnitude ($d = -0.30$), and remains so as students exit high school at Grade 12 ($d = -0.32$). As mentioned earlier, this is over three times the gender gap in mathematics for children in the United States. Furthermore, there was no substantive change across assessment waves indicating that no progress had been made closing the gap over time.

Reading in an international context

When we look to data from other countries, we see similar patterns to that found in the United States. There are two large-scale international assessments of reading achievement: firstly, the Progress in International Reading Literacy (PIRLS) measuring students in Grades 4 and 8, and secondly, the Program for International Student Assessment (PISA) measuring students near the end of compulsory schooling at age 15. In every country surveyed, the mean score for males was considerably lower than that of their female peers (i.e., the effect was universal); in no country did boys reach the standard of girls in reading (Reilly, 2021; Guiso et al., 2008). There was also a similar developmental trend to that reported in US testing data. The gender gap may start as small ($d = -0.22$ in Grade 4), but widens considerably with successive years of schooling ($d = -0.44$ by age 15). These gaps are not being driven just by a higher prevalence of dyslexia, but rather reflect poorer overall reading comprehension in boys (occurring in the middle of the ability distribution). Furthermore, despite concerted efforts made by educators to address this issue, there is no evidence that these were effective in reducing the disparity between the typical male and female student.

If, on average, boys perform considerably lower in reading in all countries, and if there appears to be no reduction in the gender gap over time, then there may be the temptation for educators and policy-makers to consider this to be an intractable and unsolvable problem. There may even be some that use this to advocate for single-sex schooling or for reducing funding to educational programs aimed at addressing the gender gap. That would be a flawed—and dangerous—line of reasoning, though. When we look at the data cross-culturally, there is actually considerable variation across countries in the magnitude of the gap (Reilly, 2012; Guiso et al., 2008). This variation highlights the contribution of structural factors that differ between countries, such as their educational practices and provision of early education programs that focus on literacy. Some countries do this better than others. Additionally, there are likely sociocultural factors contributing to this, such as parental involvement in reading to children and cultural norms around reading. Further, research is needed though to develop new educational interventions that can raise the performance of sub-clinical poor readers. A rising tide lifts all boats, and may in time reduce the disparity between male and female reading.

Writing

While the divide between boys and girls in reading has taken on high prominence, gender gaps are also present for other verbal and language abilities. Though less visible and less reported, the size of the gender gap in writing ability is actually more substantial. Part of the reason this has been previously overlooked is that there are relatively few large-scale writing educational assessments that recruit representative samples. For example, the international PIRLS and PISA assessments measure reading literacy quite well but do not seek to measure writing ability (or indeed any other verbal component, such as spelling, grammar, or language conventions). Within the United States, nationally representative samples of writing achievement have been collected by the NAEP. A recent analysis by Reilly et al. (2019) of several decades of NAEP performance found that the gender gap in writing achievement was substantial and followed a developmental trend towards a larger divide with successive years of schooling. The gender gap in writing is quite substantial when first measured in Grade 4 ($d = -0.42$) and increases for older students in Grade 12 ($d = -0.55$). By comparison, the gender gap in writing ability for students at the end of their compulsory schooling is about five times the size of the mathematics gap—yet substantially more time and resources are invested in reducing the gender gap in mathematics. Similar results are found in nationally representative samples for Australia (Thomas, 2020) and New Zealand (Parr, 2010).

Spelling

Another area where we see quite substantive gender gaps is in spelling, with girls on average scoring significantly higher than boys. Feingold (1988) examined archives of educational testing data from between 1940 and 1980, finding significant gender differences and a similar developmental trend to that observed in reading achievement ($d = -0.50$ in Grade 12). This may reflect a common underlying deficit in phonological processing which also affects reading ability. Stanley et al. (1992) reported similarly sized gender differences in large representative samples on the Differential Aptitude Test (DAT) Spelling subtest for US students, while Lynn (1992) replicated this for British students with the UK English version. Other standardized spelling tests demonstrate similar effects: for example, Reynolds et al. (2015) found similar sized gender differences on the Kaufmann Test of Educational Achievement KTEA-II Spelling subtest ($d = -0.45$).

Grammar and punctuation usage

There are also considerably-sized gender differences in understanding and usage of grammar and punctuation. Going back to earlier decades, Feingold (1988) reported girls scored significantly higher in the understanding of grammar from assessments conducted in the 1940s until testing in the 1980s (average $d = -0.43$). Stanley et al. (1992) found this as well with nationally representative samples on the Differential Aptitude Test (Grade 12 $d = -0.50$). All of these studies investigated grammar in US students, as there are no large-scale international assessments (such as PIRLS or PISA) that measure grammatical usage in a student's native language. However, it is quite likely that this effect is found globally, mirroring the pattern for reading.

Summary

In summary, there are modest but highly impactful gender differences in reading found globally, and relatively little progress has been made at narrowing the gender gap. However, these are dwarfed by gender differences in writing, as well as the components of writing (spelling and grammar/punctuation). While modest in the early years of elementary school, the gap widens considerably

with successive schooling years. This places poor writers at a substantial disadvantage in high school, particularly for courses that require students to write essays or lab reports (Zhang et al., 2019). It may also jeopardize both their prospects of entry into college/university and, once enrolled, their subsequent educational achievement given the heavy use of written assignments and short answer questions in exams. These issues have received less attention than reading and mathematics, in part because of the difficulty of measuring these other outcomes as few large-scale assessments include them. This also means many educators are unaware of the true extent of gender differences in these areas: knowing is a necessary prerequisite for tackling them in the classroom.

With an ever-crowded curriculum, it can be tempting to prioritize just reading and mathematics—particularly if other skills like writing, spelling, and grammar are not measured in state-based and national educational assessments. We know though that these skills improve with practice, and even more so when students are given guided feedback on their writing. Early writing instruction and feedback in primary/elementary school shows substantial improvement (Graham et al., 2012), but there are educationally meaningful improvements in high-school-aged students as well (Graham and Perin, 2007). The use of word processing software may highlight rudimentary spelling and grammar errors, but are not a replacement for the mechanics of grammar. Students also need guidance on high-level writing tasks like paragraphing, linking sentences, establishing an argument and writing persuasively. However, technological based writing aids can be used to supplement good writing pedagogy in the classroom, and can provide additional assistance to students with their writing outside of classroom time (Little et al., 2018). While there are many males who demonstrate great proficiency in writing ability (and some females that do not), large-scale assessments of educational achievement show that many males lag behind the typical female student. Redressing this inequality in achievement must surely be an important educational priority.

Gender differences in mathematics and science

While verbal and language abilities show a considerable female advantage, educators have long been aware that there is a male advantage in quantitative reasoning (a collective term for mathematics and science). Again, the reader is reminded that when we talk about group differences between males and females, this refers to differences on average rather than individuals. Many would have taught male students who struggled with mathematical and scientific content, and female students who excelled in these domains. Though “statistically significant” gender differences were frequently observed in educational assessments, there was little guidance for educators and policy-makers on just how *large* a difference this was, and whether this had a practical impact educationally. Additionally, it was unclear whether progress was being made over time at reducing the gender gap, as had been claimed by some researchers (e.g. Feingold, 1988).

Mathematics and science achievement in the United States

Hedges and Nowell (1995) were the first to aggregate results across multiple waves of nationally representative educational assessments to try to estimate the magnitude of gender differences in mathematics and science. Examining data NAEP data from 1978 to 1992, they observed that the gender gap in mathematics was relatively small (d 's ranging from 0.11 to 0.19), but that the gap in general science was more substantial ($d = 0.22$ to 0.33). The authors wrote that gender differences in mathematics and science “are of concern, because ability and achievement in science and mathematics may be necessary to excel in scientific and technical occupations” (p. 45). Furthermore, the authors found no evidence for any change in the extent of the gender gap over time, despite significant educational reform and social changes in gender attitudes. Numerous successive waves of PISA have been conducted since, and a recent study by Reilly, Neumann and Andrews (Reilly et al., 2015) found that there are still small gender differences in mathematics ($d = 0.10$) and science ($d = 0.13$) in modern samples. Additionally, the gender ratio of students achieving the highest level of proficiency in mathematics and science favors males, by a ratio of 2 males to 1 female. This is a far more problematic outcome, because it is from the pool of high-achievers that we would be recruiting students for STEM-degrees in college and university, and ultimately into the STEM-pipeline for the workforce. Thus, while mean gender differences are still observed and an imbalance in the gender ratio of high achievers, neither should the impression be taken that the gender gap is vast either or that it should be used as an argument in debates about single-sex schooling.

Mathematics and science achievement in an international context

This original high profile study by Hedges and Nowell (1995) helped galvanize educators, policy-makers, and researchers to make concerted efforts to address gender inequalities in mathematics and science outcomes, both in the United States and abroad. This could be evaluated periodically using large-scale international assessments of student ability such as the Trends in Mathematics and Science Study (TIMSS) measuring in Grades 4 and 8, and the Program for International Student Assessment (PISA) measuring students at age 15 near the end of their compulsory schooling. These assessments measure student achievement in mathematics and science, but also psychological and social factors such as student attitudes as well as student self-efficacy beliefs about their mathematical and scientific ability.

Results from TIMSS show that there are relatively small gender differences in mathematics and science achievement favoring males, but that these are not universal. In many countries boys and girls achieve parity, and in many countries girls greatly outperform their same-aged male peers (Reilly et al., 2017). Earlier waves of TIMSS assessments tended to find a pattern of higher male performance overall but reflected information from predominantly Western countries where gender-science stereotypes are greater (Nosek et al., 2009). This completely negates any claims that males always outperform females in mathematical and scientific achievement, that they reflect “innate” biological differences between boys and girls, or that “males are just better suited for

STEM.” Rather, it shows that sociocultural factors (such as endorsement of gender-STEM stereotypes), as well as the educational environment play a pivotal role in shaping mathematics and science (Reilly and Hurem, *in press*). As a society, how we raise and teach boys and girls shapes their worldview, and how they see themselves in relation to science.

Even at a young age, in TIMSS (Grade 8) we can start to see quite pronounced gender differences in mathematics and science attitudes (males report more positive attitudes to these subjects) and self-efficacy beliefs (males rate their mathematical and scientific ability higher than females). These presage a widening of the gender gap in mathematics and science achievement for older students, and may reflect the pernicious nature of gender-science stereotypes and self-fulfilling prophecies (Miller et al., 2018; Reilly and Hurem, *in press*). Girls who believe that STEM is more for boys begin to doubt their abilities, lose interest and motivation, and start to disengage from these courses. In later years of high school students generally have voluntary course selection of either basic or more advanced mathematics and science coursework. As noted in Eccles’ (2013) expectancy-value model of achievement motivation, students tend to select courses that they either like or that they expect they will do well in. Thus attitudinal factors like self-efficacy serve as a bottleneck limiting the number of girls pursuing STEM in the final years of high school.

We can see the direct effect of this with a widening of the gender gap in PISA results for students examined at age 15. In most waves of PISA testing, boys demonstrate significantly greater performance in mathematics (Guiso et al., 2008; Else-Quest et al., 2010) and science achievement (Reilly, 2012), especially in Western countries. Importantly though, the effect is not universal across all countries—many non-OECD countries showed significantly higher female performance in mathematics and science while the United States held one of the largest male-female differences (Reilly, 2012). As more non-Western countries participate in PISA assessments, though, we have seen global mathematics and science shift away from a pattern of superior male performance and closer to parity (OECD, 2019).

Psychological factors associated with gender differences in mathematics and science

So, while relatively little progress has been made at reducing the gender gap in STEM achievement over time in countries like the United States, United Kingdom, Canada and Australia, we now have a much clearer picture of why these gaps exist. Rather than reflecting innate gender differences in aptitude as had been claimed by some researchers (e.g. Geary, 1996), we see greater interest and, more importantly, self-confidence in males about STEM compared to females. Particularly, in countries where there is higher endorsement of gender-STEM stereotypes (Nosek et al., 2002), these limit the motivation and self-confidence of girls and women. Educational psychologists have developed brief and cost-effective interventions that can address these self-efficacy beliefs (for a review see Reilly and Hurem, *in press*), and these translate into educationally meaningful improvements in grades for girls and women (Miller and Halpern, 2013; Miyake et al., 2010; Mix et al., 2020). While the results these interventions deliver are impressive in just how large a difference they can make to female student grades, these studies are typically published in psychological rather than educational journals. Currently, educational psychologists need to make greater efforts in communicating these findings to educators and policy-makers, so as to increase their usage in the field.

Before concluding this critique of gender differences in mathematics and science achievement, there is one other issue that educators (and perhaps students) should be mindful of. The majority of evidence evaluating gender differences in STEM looks at performance on standardized tests. When we observe that males as a group have higher test scores, we draw the inference that this reflects actual differences in ability for quantitative reasoning. The underlying assumption is that test content is representative of the types of mathematical and scientific reasoning tasks students would encounter, and that it is, to the greatest extent possible, free of systematic error. But what is less frequently talked about by educational researchers is the *test and grade discrepancy* in mathematics and science (Reilly, 2019). While males generally tend to perform better than females on standardized tests, we often see a different pattern for student grades. Recall that there were small gender differences in mathematics and science achievement for US students (as measured by the NAEP). In an analysis of high school transcript data from 1990 to 2005, Shettle et al. (2007) found that girls earned significantly higher grades than boys in mathematics and all fields of science. A more recent meta-analysis by Voyer and Voyer (2014) included a broader complement of samples, including elementary/middle-school students, high school and college students. Overall across ages, females earned slightly higher grades in mathematics ($d = -0.07$) and in science ($d = -0.15$). This contrasts to the relatively small pattern of higher male performance documented earlier on standardized tests.

The exact reasons for the test and grade discrepancy in mathematics and science are complex and require further educational research. However, we cannot rule out the possibility that, especially on high-stakes standardized tests (where test anxiety are higher and all those self-efficacy doubts come in to play), girls show reduced performance but are actually equal or even greater in ability when alternate forms of assessment (such as assignments, essays, lab reports) are used. Unlike the gender difference observed for verbal and language ability addressed earlier, when it comes to science and mathematics there remains a degree of uncertainty about what the data from these standardized tests represent. Quite often in debates about the merit of single-sex or co-educational schooling, we see a selective cherry-picking of the literature to suit the worldview of the author. It is with both bemusement and some concern that, in citation searches of my own work, I find myself cited as both validating and disputing the existence of meaningful gender differences in mathematics and science. But it would be remiss not to present the entire picture with all its limitations: data from standardized tests and from grades differ. And when we make sweeping statements about boys and girls abilities in STEM, we must also remember that any observations are culturally-bound. Students raised in different countries may not hold the same endorsement of gender-STEM stereotypes, and the direction of gender gaps typically vary cross-culturally. TIMSS and PISA data present a very different view of gender differences than are found in US-centric studies.

Summary

Data from large-scale educational assessments show that significant and meaningful gender differences in mathematics and science achievement are found in students from the United States and do not appear to be diminishing over time despite educational reform and changes in attitudes to the role of women in society. Further progress must, and can, be made. Psychological factors contribute to these differences, such as endorsement of gender-science stereotypes, attitudes toward mathematics and science, as well as self-efficacy beliefs. In younger students, gender differences in mathematics and science ability are minimal, but by adolescence we can see a divide in girls' and boys' attitudes and beliefs about STEM. These presage later gender differences in objectively measured ability with standardized tests. However, we also see a discrepancy between performance on standardized tests and student grades; girls earn significantly higher grades than boys for mathematics and all science domains. This is encouraging because it suggests we may have been underestimating girls' abilities all along and parallels their own lack of confidence in their abilities. Effective evidence-based interventions to boost female performance in STEM have been developed, but have found minimal adoption in the field. Additionally, we see a completely different pattern of results when we look at mathematics achievement internationally in large-scale assessments like TIMSS and PIRLS. In many countries, female students achieve parity or even greatly exceed their male peers in mathematics and science. This invalidates claims made by some researchers that males are better suited to STEM for biological reasons, and places on educators and policy-makers an obligation to act.

Educational implications of gender gaps in educational outcomes

Given the complexities involved and the need for specialized statistical training, it is no wonder that cognitive psychology studies investigating gender differences in cognitive abilities are read by very few outside of this discipline or that when they are, they are frequently misinterpreted. Many studies are limited by small samples and selection bias (Becker and Hedges, 1988), which limits the validity of any conclusions drawn. This becomes a problem when studies are cherry-picked rather than looking at the consensus, or drawing on studies that recruit demographically representative samples. However, the educational and public-policy implications of such research are also great, and touch on important issues such as pedagogical practices, child-rearing practices, early education, affirmative action in college/university placements, and the practice of single-sex or co-educational schooling (Halpern, 2014). While we may be living in a post-truth, "fake news" world where gut instinct or ideological faith sometimes drives our decision-making, the weighty implications for educational practice and public policy behoove us to evaluate the evidence carefully. For some types of cognitive tasks, gender differences are comparatively small and for others the gender gap is quite large. In fact, for tasks like writing and grammar, the effect sizes are so large that it may prompt us to reconsider the way in which these skills are taught and practiced inside and outside of the classroom. Good writers are not born but rather made: writing is a skill that improves with guided practice. This is especially true when direct feedback to the writing is given in a timely fashion, and students are then asked and supported to revise and edit their work (Parr and Timperley, 2010). While one gender may be predisposed to higher achievement, evidence-based interventions are available to mitigate this and reduce the gender gap, including the use of technology (Graham et al., 2018; Little et al., 2018). We also need to better support readers who come in at sub-clinical levels of reading impairment. This is a problem that should be approached collaboratively, with parents and early educators working hand-in-hand.

Prevailing gender stereotypes that mathematics and science are for men or that boys have a natural aptitude for them are very much alive in the minds of students, their parents, and their teachers. Yet, when we have a look at the actual evidence on the subject, the gender gap in mathematics and science is actually comparatively small in size when related to reading and writing. It is certainly not a trivial difference (especially when you look at the gender ratio of higher achievers, which falls roughly 2:1), but neither is it so large that gender parity is unattainable. When we look to international studies, in many countries girls meet or even greatly exceed boys in mathematics and science. But at least in Western nations, at some time during early high school, we start to see a decline in girls' general attitudes toward science while boys remain high. Data from self-reports tells us that girls start to doubt their mathematical and scientific aptitude as well. This directly impacts subject selection and serves as a bottleneck, leading to an underrepresentation of women pursuing STEM coursework in college and entering the STEM workforce. Educationally, we need to better support and nurture girls' interest in science and their self-confidence. The test and grade discrepancy shows us girls and women have the natural aptitude for STEM—even though they may sometimes doubt so themselves.

Conclusions

Reasonable people may reasonably disagree on how best to educate children, adolescents and young adults. Still, we should at least keep an open mind and model those same critical reasoning skills we wish to imbue our students with. Educators should be wary about reviews that "cherry-pick" the literature, or cite only very small and highly select samples. Evidence from large-scale, nationally representative samples show there are small but non-trivially-sized gender differences in mathematics and science favoring males. There are also far more pronounced differences in verbal and language abilities favoring females. Biology may well contribute to gender differences in reading and writing (as the literature shows moderately large differences are found cross-culturally), but it is a poor explanation at best when it comes to gender differences in mathematics and science since there are many countries where females outperform males. I have attempted to outline the evidence base for gender differences in cognitive abilities without wading too heavily into the partisan debate on single-sex schooling; on this matter it is difficult to persuade a mind

that is already fixed while a more open one can find the issue debated elsewhere. However, the review does present (at the time of writing) the most up-to-date view of gender differences in educational outcomes for verbal and quantitative reasoning. There is little evidence of any decrease in the magnitude of gender gaps in educational achievement at present, but I remain hopeful that this will not always be the case.

Acknowledgment

I thank my colleague Dr. Aida Hurem for her helpful suggestions and proofing of this manuscript.

Orientation

This chapter provides an overview of research and practice in the field of networked learning. It describes some of the core characteristics of the field, summarizes the history of its development and identifies connections with related work that goes under other names, such as online or blended learning. The main part of the article introduces and discusses key concepts and identifies some foci and approaches to research. Examples of practical applications are provided.

Taking a network perspective

For a researcher interested in learning, taking a network perspective is a deliberate choice. It is possible to examine learning and related educational phenomena from other perspectives – spatial, systems, ecological, architectural, market and hierarchical, for example. Different framings and combinations of framings make it easier to see some kinds of patterns, and harder to see others. The choice of perspective can also affect the kinds of relationships and explanations that may be readily advanced. For example, the use of a spatial perspective foregrounds location, presence, proximity, place-making and containment. It is common, though often implicit, in accounts of classroom processes. Similarly, a systems perspective foregrounds dynamic change, positive and negative feedback, and emergence. Those choosing a network perspective are foregrounding connections.

Exactly what is connected in a network can also be open to definition by the researcher. Networks consist of nodes and connections between nodes. The connections are also referred to as links, ties or edges. Each node may represent a person, an organization, a device, an idea – indeed, almost anything can be represented as a node and almost any of its relations to other nodes can be represented as a link. The question for the researcher is whether this way of looking at a particular set of phenomena of interest provides insights that would be hard to obtain in other ways. As Jones (2004, 82) puts it: “when we analyze in terms of networks, we also help to perform networks into being.”

Some networks can be said to have an existence independent of a researcher's gaze. Obvious examples are artificial networks such as those used for electricity distribution, for transport (e.g., road, rail and airline networks) and in digital communications (e.g., the Internet). Everyday use of network terminology can also lead us to think that networks exist in nature – as with a spider's web or among the synapses and neurons of an animal's brain. But even with these examples, there is an element of researcher choice about how, exactly, to carve up reality.

It is not just researchers who can bring networks into being. For example, over the last 25 years, a number of educational practitioners have chosen to describe their work in terms of “networked learning”. Part of their professional activity helps bring into being various kinds of “learning networks”, which are then open to researchers to study.

It is often said that we live in a networked world (Castells, 1996, 2001; Rainie and Wellman, 2012). In this regard, Dohn (2018) points to six different senses with which “networked” is used:

1. Linking geographically dispersed places through an infrastructure of connected computers,
2. Communication that increasingly relies on the mediation of the Internet,
3. Information processing – including retrieval, exchange and archiving – that is carried out between machines, with little human involvement,
4. Denoting the way that “our lives play out in hybrid spaces where physical and virtual resources integrate in complex ways to support us in our activities” (op. Cit., p. 5),
5. Acknowledging the importance of connections between people – that we have personal networks and engage with a range of networks relevant to different areas of our lives, and
6. To note that events and situations are linked to other events and situations by technologies and other people.

The fifth and sixth of these senses are not intrinsically dependent on computers and the digital. Though the rapid development and take-up of digital technologies have changed how people and events connect, networks predate the digital. Indeed, there is a growing body of research in areas such as history, archaeology and economics using network techniques to understand trade, communication, and kinship networks, running back into antiquity (Hodder, 2012; Knappett, 2013). Some of these networks have/had an explicit learning function, as in networks of scientists and scholars (Collar, 2013; Pietsch, 2013). And one might argue that virtually all networks involve some significant incidental learning, such as when traders learn to build trust and to share information up and down supply chains about the quality of products and about market preferences (Duguid, 2005; Hancock, 2005). Goodyear (2014) notes resemblances between the networks based on London’s 18th century coffee shops, with their libraries and magazines, and the functioning of some contemporary learning and innovation networks based on social media.

Social scientists interested in networked organisational forms have observed that networks can be said to possess some advantages over the two best known alternatives: markets and hierarchies. Networks combine some of the flexibility of markets with some of the predictability of hierarchies.

We define a network form of organization as any collection of actors ($N \geq 2$) that pursue repeated, enduring exchange relations with one another and, at the same time, lack a legitimate organizational authority to arbitrate and resolve disputes that may arise during the exchange. In a pure market, relations are not enduring, but episodic, formed only for the purpose of a well-specified transfer of goods and resources and ending after the transfer. In hierarchies, relations may endure for longer than a brief episode, but a clearly recognized, legitimate authority exists to resolve disputes that arise among actors.

Podolny and Page (1998, p. 59).

Many contemporary learning networks, as with some other kinds of digitally mediated networks and online affinity groups, have an organizing authority of some sort, though that authority may be quite distributed, fragile and limited in its ability to resolve disputes. Authority is more centralized and visible in learning networks that are organized as part of formal education provision, where networks take on some of the characteristics of hierarchies. Authority is more diffuse in informal self-organizing learning networks.

As with the early (predigital) networks found in areas such as trade and scholarship, the predictability of life in contemporary digital or hybrid networks depends heavily on reciprocity and trust. Indeed, network members typically spend a good deal of time maintaining mutually supportive relationships and most long-lasting networks have a repertoire of methods for building consensus and resolving differences through discussion. Building trust and creating shared understandings involves a good deal of information exchange: much more so than we find with markets. The boundaries of networks are easier to modify than is usually the case with hierarchical organisations. This combination of rich communication and flexible boundaries gives networks advantages over markets and hierarchies in times of change. One can argue that part of the attraction to networked ways of thinking and organizing comes from a view that we are living in dynamic, unpredictable times.

Learning networks and networked learning

What distinguishes a learning network from networks in general? Linda Harasim was among the first educators to popularize the term (e.g., Harasim et al., 1997) but neither she nor her collaborators came up with a satisfactory definition (Carvalho and Goodyear, 2014). The best approach to characterizing a learning network may be to start with “networked learning”. There is now a well-established field of research and development on networked learning, with biennial conferences and a book series. Until recently, the customary definition of networked learning, used in calls for papers and introductory texts ran as follows:

We define ‘networked learning’ as learning in which information and communications technologies are used to promote *connections*: between one learner and other learners, between learners and tutors; between a learning community and its learning resources. Some of the richest examples of networked learning involve interaction with on-line materials and with other people. But use of on-line materials is not a sufficient characteristic to define networked learning.

Goodyear et al. (2004, pp. 1–2).

One might then say that a learning network is the organisational form in which networked learning takes place. An updated version of the customary definition is given later in this article, but the fundamental idea of a learning network remains intact.

Productive learning networks

Carvalho and Goodyear (2014) extended the concept, in order to speak of productive learning networks. Here “productive” is not used as an evaluative term – the antithesis of unproductive or ineffective. It is used to highlight the creative and constructive aspects of networked learning, with an emphasis on learning through the co-creation of knowledge (production rather than consumption), and on self-realization and identity formation through participation in shared work.

Learning network architectures

Carvalho and Goodyear’s (2014) architectural approach to the study of learning networks is motivated by a goal of analyzing working examples of learning networks in order to extract reusable design knowledge: knowledge that is useful to people who have responsibility for helping other people learn together. They argue that architecture provides ways of acting and reasoning that are characterized by indirection, invitation, epistemic fluency and an ability to move fluidly across scale levels.

Architectural design works indirectly in that it creates built forms that are intended to have effects on how people act, think and feel. Like other areas of design, architecture knows how to work through invitation – it offers suggestions – rather than through compulsion. This designerly combination of invitation (e.g., suggesting worthwhile tasks) and indirect action (e.g., creating supportive learning environments) can help educators find ways of working skilfully with dynamically changing configurations of learner agency and structure.

Architectural practice also involves multiple forms of knowledge and combines diverse ways of knowing (e.g., from materials science, finance and art history). By extension, people who are designing to support networked learning, and to help a learning network flourish, need to know how to combine diverse kinds of knowledge, created through diverse epistemic practices, from across the learning sciences (Goodyear et al., 2016). Finally, an architect’s attention moves quickly back and forth between grand plans and the resolution of fine details. In hierarchical organisations, educational and otherwise, divisions of labor can render this fluid movement between high-level goals and implementational details very difficult. In contrast, architects know how important it is to get the devil out of the details.

The design knowledge produced by architecturally-informed analysis can be formalized and shared in a number of ways, including through design principles (e.g., Dohn et al., 2020) and design patterns (Goodyear, 2005; Goodyear and Retalis, 2010; Mor et al., 2014.) Design principles are general statements aimed at supporting reasoning about connections between desired outcomes and designable artifacts. Design patterns describe well-tested design solutions, and help explain why they work in specific contexts.

Personal and organisational perspectives

Learning networks can be analyzed and understood from at least two perspectives: a first-person perspective, in which the experience of a single person is foregrounded, and where their view of the network(s) in which they are involved is given primacy, and a holistic or organisational perspective, in which structural and/or aggregate data are gathered about an entire network. Sociological studies of networks refer to the first kind in terms of “ego networks”. In networked learning research, “personal learning network” and “professional learning network” refer to ego-networks used for learning. (See Practical Applications in the Section on **Practical applications: examples from teachers’ professional learning**, below).

Communities and networks

The terms “community” and “network” are sometimes used as synonyms, as with “online learning community” and “learning network”. But sometimes the broader connotations of the terms make one preferable to the other. For example, “community” can suggest stability, closure and an inward-looking orientation, whereas “network” can imply a degree of openness and flux. “Network” implies travel – of ideas, people, goods or messages. “Community” does not.

A brief history of networked learning

Origins

The origins of networked learning can be traced back to experimental work by Murray Turoff for the US Office of Emergency Preparedness. Turoff and colleagues at the New Jersey Institute of Technology developed a system called EMISARI (the Emergency Management Information System and Reference Index) in 1970–71, based on earlier use of Delphi techniques to solicit advice from

geographically distributed teams of experts. EMISARI offered many of the functions that we now associate with online discussion systems, or computer-mediated communication systems: sharing messages and other texts, discussion threads, tagging texts, search tools and notifications of updates. Until the early 1980s, EMISARI and its successor system (EIES: the Electronic Information Exchange System) were seen mainly as tools for expert users, including networks of scientists working on fast-moving topics. In 1982 came the first use of EIES in teaching, creating what [Hiltz \(1986\)](#) dubbed a “Virtual Classroom”. A number of researcher-practitioners pioneered various pedagogical and technological arrangements through the 1980s, mainly in the United States, though sometimes connecting up with participants in other countries. For example, [Riel and Levin \(1990\)](#) describe several pilot experiments using email to connect teachers and schools, including in international networks. [Quinn et al. \(1983\)](#) provide some models for analyzing differences in discourse among students in networked and face-to-face classes.

By the early 1990s, the use of digital networks to connect students, teachers and learning resources was becoming more widespread, especially at the university level and for postgraduate and professional development programs of various kinds. Experimental work was reported under a number of different labels, often anchored in technological rather than educational choices (e.g., [Mason and Kaye, 1989](#); [Steeple et al., 1994, 1996](#), writing about “computer-mediated communications” or [Hardy et al., 1994](#), on “computer conferencing”). Ten years later, the educational lexicon had grown to accommodate “online learning” and “online teaching”, “e-learning” and “blended learning” ([Clark and Mayer, 2002](#); [Harasim et al., 1997](#); [Salmon, 2000](#); [Thorne, 2003](#)). These particular streams of educational innovation and associated research did not necessarily attend to the forms of social learning that characterize networked learning, an exception being the subfield of computer-supported collaborative (or co-operative) learning – known widely as CSCL ([Dillenbourg et al., 1995](#); [Koschmann, 1996](#); [O’Malley, 1995](#)). Within CSCL, the vast majority of research has focused on the dynamics of small group learning. Research at the scale of communities or extended networks has been rare ([Goodyear et al., 2013](#)). It is this combination of (a) insistence on the importance of social learning and (b) social learning at scale, that distinguishes the area of networked learning research and practice.

Networked learning crystallized in the late 1990s by distinguishing itself from developments in digital education that were undermining human connectivity— developments that threatened to reduce education to the production, delivery and consumption of ‘content’ (‘online materials’).

Networked Learning Editorial Collective (NLEC) (2021, p. 315).

Research and development in networked learning

In the UK and the rest of Europe, a network of networked learning researchers began to take shape in the late 1990s, brought together around a series of biennial conferences and resourced, in part, by some linked research project teams ([Goodyear, 2014](#); [Hodgson and McConnell, 2019](#); [McConnell et al., 2012](#)). Many of the researchers shaping this field were/are also educators, and so accounts of networked learning often mix normative and descriptive statements. In other words, the teacher-researchers involved have strong views about pedagogy and educational relations. The texts they produce combine statements about what is, and what ought to be. For example, in analyzing the distinguishing characteristics of an MED program in Networked Learning at the University of Sheffield, [Hodgson & McConnell \(2019\)](#) identified six key features:

1. A commitment to democracy and openness in the educational process.
2. Self-managed learning, allowing freedom to learn.
3. A real purpose to cooperative activities.
4. A supportive learning environment.
5. Collaborative assessment of learning.
6. Ongoing review of learning activities.

They see these as being actualized through work on four design components: a learning community, action research, learning sets and workshops.

Abstracting from their experiences as networked learning teachers and researchers, [Hodgson and McConnell \(2019\)](#) offer eight principles to underpin networked learning.

1. The focus is on learning which has a perceived value to the learners.
2. Responsibility for the learning process should be shared (between all actors in the network).
3. Time has to be allowed to build relationships.
4. Learning is situated and context dependent.
5. Learning is supported by collaborative or group settings.
6. Dialogue and social interaction support the co-construction of knowledge, identity and learning.
7. Critical reflexivity is an important part of the learning process and knowing.
8. The role of the facilitator/animator is important in networked learning.

From the outset, networked learning has embraced a strong, though not always explicit, critical and emancipatory tradition. The customary definition, reproduced above, worked well as a way of providing focus for the first 20 years, but the rationale for its emphasis on connections was not explained; it was silent on the question of purpose. In an effort to update the definition and address this omission, a team of networked learning researchers jointly created the following aspirational statement.

Networked learning involves processes of collaborative, co-operative and collective inquiry, knowledge-creation and knowledgeable action, underpinned by trusting relationships, motivated by a sense of shared challenge and enabled by convivial technologies. Networked learning promotes connections: between people, between sites of learning and action, between ideas, resources and solutions, across time, space and media.

NLEC (2021, p. 320).

It remains to be seen whether this statement, or something like it, will be adopted as a description of the character and purposes of networked learning, going forward. A broad range of views on the matter can be found in NLEC et al. (2021).

The transition to social media and to a postdigital world

It is perhaps surprising that some of the preoccupations to be found in research and descriptions of innovative practice in the early days of networked learning are still visible in contemporary literature. Interest remains strong in such topics as the role of teachers, trust in peer learning, the nature of discourse and argumentation, identity formation, digital exclusion, and social justice. This steadiness of gaze has been maintained during a 20–30 year period in which the technologies used have changed almost beyond recognition, in terms of performance, usability, access and familiarity. Writing about networked learning in the 1990s was work from the margins. Now, widespread use of social media – Twitter, Facebook, Instagram, Tik-Tok and the like – means that learning from other people over digital connections is almost ubiquitous and goes almost unremarked. This raises interesting questions about differences between intentional and incidental learning (and teaching) and between formal, non-formal and informal educational arrangements.

Accelerating availability of the technologies underpinning networked learning has also been changing people's expectations and habits, such that much of what people do, and expect to be able to do, involves quite complex arrangements of digital and material things. The rapid interpenetration of the digital and material worlds has caused some researchers to argue that we are now in a post-digital age: one in which digitalization remains important and worth continuing scrutiny, but in which the binary distinctions between "real" and "virtual" are no longer helpful (Fawns, 2019; Macgilchrist, 2021; Sinclair and Hayes, 2019).

Approaches to research and development

Those who research networks use a variety of methodologies, with a range that includes approaches that use sophisticated mathematical techniques to analyze network structures and approaches that elicit nuanced accounts of participants' experiences (see e.g., Barabási, 2002, 2016; Jones, 2015). The fact that much of the research in networked learning is carried out by educators inquiring into their own praxis means that a good deal of the work is relatively small scale, locally focused and sensitive to context (Goodyear et al., 2006; Jones, 2015; Levy, 2003). This section provides a brief summary and follow-up references to five approaches: analyzing online conversations, understanding participant experiences, social network analysis, mapping the quality of participation and activity-centred analysis and design.

Analyzing online conversations

The persistence and searchability of digital texts afford research on the structure of educational discussions. This opportunity was seized quite rapidly by researchers already interested in (face-to-face) classroom discourse, so there is now a 40-year corpus of research examining what is said by whom, with what frequency and what results (Häkkinen, 2013; Hara et al., 2000; Hardy et al., 1994; Henri, 1992; Howell-Richardson and Mellar, 1996; Ouyang and Chang, 2019; Quinn et al., 1983; Schrire, 2006).

It is impossible to summarize briefly the findings emerging from this literature, especially given the diversity of pedagogical strategies, educational designs, aims and purposes, age ranges and technological devices and infrastructures involved. That said, there are some questions to which research frequently returns, often deriving similar answers. These include (a) the importance of shared understandings of the intentions of teachers and students in networked learning discussions, (b) the value of appropriate modeling and scaffolding for students' participation in such discussions, (c) the significance of ethics of participation, particularly in avoiding the marginalization of some subsets of participants (Dohn et al., 2018; Jones, 2015).

Understanding participants' experiences

Within research on networked learning, there is also a well-established and strong line of research into the experiences of participants, including the experiences of those in formal education who have recognized roles as students or teachers. Much of this research, especially in higher education, has used a phenomenographic approach, based on the ideas and methods of Marton and colleagues (Marton, 1984; Marton and Booth, 1997). For example, Jones and Asensio (2002) studied the networked learning design experiences of university teachers. Roberts (2003), in the United Kingdom, and Gonzalez (2010), in Australia, identified a hierarchy of conceptions of online teaching held by university lecturers. Cutajar (2017) and Ellis and Goodyear (2010) have similarly identified more and less sophisticated conceptions of networked learning among university students. Related research has

made innovative use of digital ethnography to create detailed accounts of participant experiences in a range of networked learning situations (Hodgson and Watland, 2004; Jones et al., 2008).

(Social) network analysis

There is much more to be said about a network than can be inferred from the experiences of participants. Nor can all its characteristics be defined as aggregates of the actions or wishes of participants.

Network-based analysis and reconstruction methods can offer insight into local and global properties of systems of interconnected objects, which can neither be discovered by studying the interacting agents individually or in pairs, nor by studying the average properties of the system as a whole ... network models have the power to facilitate structural comparison across different scales and source materials and to formulate hypotheses and models for further exploration.

Sindbæk (2013, p. 72).

Sindbæk was speaking of network analysis in archaeology, but his claim is also sustainable in relation to learning networks. A number of educational researchers have applied mathematical methods for analyzing and modeling learning networks, and indeed social network analysis (SNA) and related methods have become an important part of the field of learning analytics (De Laat et al., 2007a, b; Gunawardena et al., 2016).

Figs. 1–3 have been constructed to help explain the kinds of analysis and visualization work that can be done, and to give examples of some of the sorts of insights that can be generated. The illustration created for this purpose is set in a formally organized learning network and offers a simplified representation of interactions between a class of 32 students who are using an online discussion board.

Each student is shown as a node. A tie is shown between a pair of nodes if, and only if, the students concerned have engaged in an exchange of messages. An exchange of messages is defined in this example as: (a) a student posts an online discussion item, (b) another student posts a response to that item, building on what the first student has written, (c) the first student posts an acknowledgment, extending the line of discussion further. Fig. 1 shows the ties (exchanges of messages, as just defined) at the end of the first week. It reveals that most students have been involved in at least one exchange. (Students A and Z are the only exceptions.) A few students have been involved in exchanges with more than one other student. (Students C and G are examples.) Fig. 1 is typical of classes in which the first week's set task is to post, respond and acknowledge and where most students have (a) satisfied the task requirement, but no more and (b) have done this reciprocally, in a pair.

Fig. 1 Network connections established through online discussion after one week.

Fig. 2 Network connections after two weeks.

Fig. 3 Network connections toward the end of the course.

Fig. 2 shows the situation at the end of the second week. It reflects a suggestion from the class teacher to the students that they should work in small groups, of four to six members. So, for example, students A to E appear to have formed a group of five; M to R a group of six; S, T, U and V a group of four. All students have now engaged in at least one exchange of messages. It is not clear, at this point, whether student F is a member of a group.

Fig. 3 shows connections between members of the class after several weeks of discussion. The width of the line for each tie is proportional to the number of exchanges between the pair of students linked. So, for example, there have been a substantial number of exchanges between A and C, and between R and P. Fig. 3 shows that the small group structure that commenced in week 2 has persisted: many of the exchanges have been within groups. But there have also been exchanges between students in different groups. For example, student F has been involved in a single exchange with five other students, in four different groups. Network analysts refer to the connections represented by thick lines in Fig. 3 as “strong ties”, whereas those characterized by few exchanges are “weak ties” (Granovetter, 1973; Jones et al., 2008; Ryberg and Larsen, 2008). It is important to note that weak ties can be useful in passing information between different groups, so F may well be playing an important role in this network.

Of course, there are strict limits to what can be inferred by an outsider solely from the presence and absence of connections. Student F may have been tasked by the teacher to act as a rapporteur, harvesting and sharing information between groups. Or it could be the case that student F’s messages are banal or offensive and nobody wants to engage in an ongoing correspondence with them. Finding out more about the nature of the discussion, exchanges and relationships requires one to look at the texts exchanged, not just the pattern of connections. For this reason, (social) network analysis of this kind is often complemented with analysis of the content of messages (De Laat et al., 2007b).

Mapping participation

This approach to researching learning networks focuses on characterizing the nature of collaborative encounters – where people choose to collaborate to accomplish some shared aim, which may be, for example, professional development, or planning joint action of some kind. It is particularly useful in tracking the evolution of a learning network over time. The original ideas about mapping intentional collaboration come from Manzini (2015) and were applied to professional learning networks in Goodyear (2019). The approach works with four dimensions: degree of active involvement, degree of collaborative involvement, strength of social ties and relational intensity. These are explained in Table 1.

Dimensions 1 and 2 allow one to map participant involvement (PI), while dimensions 3 and 4 capture interaction quality (IQ). Figs. 4 and 5 show how PI and IQ can be mapped, for any one network, at any stage in its history. The explanation is from Goodyear (2019).

Fig. 4 maps the space of participant involvement (PI): who does what, with whom and how. A high level of active involvement coupled with a low level of collaboration can be characterized as a DIY (do-it-yourself) arrangement. Self-drive car-sharing schemes are a typical example: high user input to the service/activity itself, but little or no contact with other people. In the networked learning area, we could think of self-directed learning from online repositories of instructional videos as an analogous case. Low levels of both active involvement and collaboration are typical of mainstream service delivery. Using a “ride sharing” service or getting a quick answer to a question via an online chat-based helpdesk are examples here. Higher levels of collaboration, coupled with low levels of personal active involvement in the service itself, are commonly found with co-managed services, as when a group of people work together on policies or high-level management issues but do not get directly involved in actual service delivery. A housing co-op which employs maintenance and cleaning staff is an example, or a university management team whose members are

Table 1 Four dimensions for mapping collaborative encounters.

(1) Degree of active involvement	Participants may take quite a passive role – partaking of a service provided by another person – or they may more actively co-produce the service, fielding personal resources as they do so (time, energy, attention, skills, expertise, etc).
(2) Degree of collaborative involvement	This may range from close to zero (doing almost everything alone or virtually alone) to intense (engaging closely with others).
(3) Strength of social ties	May vary from weak to strong. Weak ties can be created quite quickly and may not persist; strong ties take time and commitment.
(4) Relational intensity	Characterizes the affective and empathetic qualities of the encounter, the depth of the relationship, the degree to which people treat each other as fellow human beings rather than (say) seller and buyer.

Fig. 4 Mapping collaborative encounters – participant involvement (PI).

no longer involved in teaching. Finally, **Fig. 4** situates co-production as involving high levels of active involvement in production of the service itself and of collaborating with others. People who both organize and do voluntary work in a community garden are in this zone, as are people who collaborate within a self-managed learning network. It is important to point out that high levels of active or collaborative involvement are not in themselves virtuous. It would be exhausting to live one's life entirely in that way. The key issue is to make, and help others make, considered choices about collaborative engagements.

Fig. 5 maps a similar space but for interaction quality (IQ). This is a less elaborated construct in Manzini's work: the space is rendered simply in terms of the strength of social ties and the quality of the relationship (deep, warm and personal or formal and rule-defined). A reason for this may be that the dimensions of PI have the capacity to frame deliberate action in advance, whereas those of IQ reflect something more emergent: qualities that become clearer in and after the fact. Indeed, Manzini's examples say more about the warmth or depth of connection in an encounter as experienced, and rather less about characteristics of the arrangements that might be recognisable or clearly specifiable *a priori*. (One can make a deep and warm connection with someone even in a highly regulated, formal situation.) As with PI, none of these arrangements is intrinsically better. For example, being able to collaborate in weak-tie situations makes life more open and less tribal.

Activity-centred analysis and design (ACAD): design research and the creation of design knowledge

The kinds of research methods and tools sketched above can be used for a variety of purposes. This final sub-section links them into a higher level framework known as ACAD. ACAD is a meta-theoretical framework that can be applied to understand and improve the functioning of a learning network (Goodyear et al., 2021). There are two distinctive features to ACAD. First, the framework

Fig. 5 Mapping collaborative encounters – interaction quality (IQ).

insists on a clear separation between (a) “design time” or a forward-looking design perspective and (b) “learning time” or a retrospective examination of actual, emerging experiences. The design perspective is taken by people who have a stake in supporting and improving the functioning of a learning network. It looks at a set of representations of the network and involves discussions about what can and should be changed (added, removed, fine-tuned, and so on). Any discussions held, and commitments made, need to pay sharp attention to pragmatics, to what can be changed through upfront design work. The retrospective analysis attends to the actuality of what has been occurring in the network – real-world activities that have real consequences for participants, including what they have learned and how. Ideally, this analysis and design work is cyclical, paced by the rhythms of the network. The second distinctive feature of ACAD is that it divides up the entities that situate learning activity into three kinds of design components: tasks (epistemic design), physical structures (set design, which includes material, digital and hybrid) and social structures (social design). At “design time”, some changes can be made to the entities in each of these groups. For example, the specification for a task may be modified, a new set of online resources may be added, and recommendations about group-structures or divisions of labor may be revised. At “learning time”, these all become entangled in the activities of the network. It makes sense to divide up the three different kinds of design component, because different kinds of reasoning are needed in each case. But, in the actuality of networked learning activities, they become harder to separate.

Practical applications: examples from teachers’ professional learning

This section provides some examples of networked learning in practice, focusing on teacher learning in professional networks. Recent surveys of this rapidly developing but still under-explored area of work can be found in [Kelly et al. \(2016\)](#), [Macia and Garcia \(2016\)](#), [Lantz-Andersson et al. \(2018\)](#) and [Kelly \(2019\)](#). Teachers’ engagement with others in networks for learning and professional development has been studied in a range of ways, using perspectives that foreground ego-centred personal networks, informal or self-organized networks and externally organized and managed networks. [Lantz-Andersson et al. \(2018\)](#) find a number of common themes in both formally organized (“top down”) and informally organized (“bottom up”) networks. For example, the value teachers report from network participation often resolves into one or more of: sharing information relevant to professional practice; benefitting from the filtering and curating work of peers (avoiding information overload); feeling collegial support – emotional and as a prompt to reflection – and encouragement to experiment and take risks.

Personal learning networks (PLNs)

[Trust et al. \(2016\)](#) report a survey of 732 schoolteachers, in which teachers were asked about their personal, professional learning networks (PLN). In this case, what is being asked about is each teacher’s personal (ego-centred) network: its nature, the purposes it serves and its effects, if any, on the educational activity and outcomes of the teachers’ students. [Trust et al. \(2016\)](#) argue that PLNs align with a “whole teacher” approach to professional development (PD) – in contrast with other forms of professional development that (can) only address a subset of any one teacher’s needs. Other forms of PD can suffer from problems of decontextualization, especially when the PD is offered outside school, and to meet the assumed needs of “typical” teachers, rather than the specific needs of actual teachers. Such forms of PD are necessarily piecemeal, unevenly and uncertainly distributed in time and space. In contrast, and by their very nature, PLNs are assembled and maintained by each teacher, in ways that match their own sense of the full range of their needs. This is not to say that teachers always succeed in managing their PLNs efficiently and effectively. Nor are they always able to learn what they need, or what their students need. The key distinguishing feature of PLNs, however, is that they adjust dynamically to changing needs and they integrate around each individual teacher. Given this personal focus, it is not surprising that PLNs are themselves diverse, typically involving multiple platforms, tools and media; often including both online and face-to-face interactions, and having multiple purposes. For example, in the [Trust et al. \(2016\)](#) survey, teachers revealed that the other people in their networks were drawn from many different areas of work and life – not just education – and from other school systems, including school systems in other countries. Teachers reported that their PLNs gave them a sense of being (internationally) connected educators, able to identify with communities of other enthusiastic teachers.

Teachers’ use of PLNs is widespread internationally, quite likely mirroring social media habits and Internet usage more generally. For example, [Le et al. \(2021\)](#) report a study of how English as a Foreign Language (EFL) teachers in Vietnam use social media for professional learning purposes. As with studies from other countries, the main uses include searching for, acquiring, and sharing teaching resources and building professional relationships.

Externally organised/managed networks

[Kelly et al. \(2018\)](#) describe *TeachConnect*, a platform created collaboratively by eight Australian universities to support newly qualified teachers entering the teaching profession. These first years in schools are well-documented as problematic, for many teachers. Poor experiences in classrooms and staffrooms lead significant numbers of early career teachers to leave the profession. *TeachConnect* was designed, in part, to help address this problem through mentoring, community support, help with induction and other forms of knowledge sharing (see also [Kelly et al., 2016](#)). [Kelly et al. \(2018\)](#) used the ACAD framework, described in the Section on **Activity-centred analysis and design (ACAD): design research and the creation of design knowledge** above, to structure their design and evaluation work. A major challenge identified during the early design work was the difficulty of creating trust within very

large networks. After some experience with the platform, Kelly et al. (2018) also noted the difficulty of securing ongoing participation from the majority of those who signed up. (Only about 25% of those registering were ongoing participants.) ACAD helped the team designing and running the network to identify some priorities for the next rounds of redesign, focusing particularly on aspects of social design.

In the space between PLNs and national networks, one can also find learning networks organized around action on a smaller scale. For example, van Amersfoort et al. (2019) report a study of two teacher learning and development networks, each based around a cluster of schools and each involving teachers, school managers and researchers. The networking arrangements were informed by a number of principles, such as that the teachers' networked learning should be embedded in their daily practices, promoting the sharing of problems of professional practice, and candidate solutions; the teachers should shape their own learning experiences, deciding on topics, timing and relationships, and networks should be established around particular problematic areas, but be free to evolve new interests and purposes over time. A special focus in this study was to identify different forms of value created within the network, using the model elaborated by Wenger et al. (2011). Notably, the authors found that teacher participants benefited through reframing their understandings of professional learning, including their sense of the value of learning from peers.

Heterogeneous networks

The discussion of networks thus far, in this chapter, has been restricted to homogeneous networks in which the nodes are of the same kind: people, or organisations, for example. Researchers also study heterogeneous networks, in which the nodes vary in kind. Notably, researchers may represent, as a network, the mix of people, devices, tools and artifacts involved in some selected event, process or practice. Purposes vary, but such networks can be used to explain causal connections, the propagation of effects, lines of influence and/or dependence, and so on.

The following example shows what we mean, and also serves as a further illustration of learning networks in action. Fig. 6 is based on materials from a study reported in greater detail in Goodyear and Carvalho (2019). The study involved an ethnographic approach to researching the role of iPads in the education of students who were learning to be paramedics. The initial focus of the study was on the specific contribution that use of the iPads made to the students' learning during a simulated mountain-rescue exercise. The exercise was held in a relatively remote upland area, over two days. For many students, this was their first experience of such an environment. Other participants in the exercise included some very experienced mountain rescue personnel and actors playing casualties.

The researcher was briefed to take an exploratory approach, roving around while the exercise unfolded, making field notes, and trying to identify and describe as carefully as possible the networks of things that seemed to influence the activities and their outcomes. The researcher's field notes mentioned that the iPads were used, though not often. Table 2 captures other tools and devices that featured in the exercise.

Fig. 6 Heterogeneous network: mountain-rescue exercise.

Table 2 Tools and people involved in the mountain rescue exercise.

<i>Tools for navigation and communication</i>	<i>Tools for “treatment” of simulated casualties</i>	<i>People</i>
Compasses, maps, GPS devices, torches, whistles, ropes, binoculars and walkie-talkies	Stretchers, bandages, scissors, watches (for measuring a pulse), stethoscopes, medications, and syringes	Actor/casualties (semi-skilled), the mountain rescue volunteers (very skilled), the tutors (semi-skilled) and the students (often lost, cold, and confused; worried about breaking the iPads)

Of course, the design and evolution of this exercise also necessitated being in the mountains.

The difficulties of traversing rough terrain, locating a casualty when hidden in a valley or by vegetation, coping with poor visibility and communicating without mobile phones all played a substantial role in the exercise. Proper clothing is also important. A conventionally-minded instructional designer might be forgiven for thinking that good boots and a warm, waterproof coat are things for the students to provide. But those who forgot these important items were unable to complete the exercise. And which instructional design guideline tells you that fingerless gloves are useful when trying to use an iPad on a cold mountain?

Goodyear and Carvalho (2019, pp. 58–9).

Two points can be made here. First, the conventional educational technologist’s framing of researching this exercise caused the initial focus to be on a single kind of device (the iPad) and on gathering evidence of whether or not it made a positive contribution to the students’ learning. This narrow aperture would have rendered invisible all of the other devices and people involved in the exercise. It is also far from clear that any simple measure of learning outcome would have shed light on the role of the iPads. Second, the opportunity to pay close attention to the activities enabled the research team to (re-) construct a depiction of the outcomes of the exercise: outcomes that were not expressed in these terms in any of the course’s documentation, and which largely remained implicit or (at best) were caught up in fragments of briefing and debriefing discourse. In short,

Successful participation in the exercise involved:

- Learning to use each of the tools listed in [Table 2](#), at least with sufficient fluency to be able to act according to the established protocols, but ideally with a level of automaticity that binds tool and action in a smooth flow
- Weaving the use of the tools into an integrated set of activities, involving smooth effective action, co-ordination with others, focusing on the priority goals, etc.
- Turning the individual and aggregate experiences of the exercise into learning that lasts.

The combination of observant participation and a network sensibility eventually enabled the research team to map a heterogeneous set of interdependent actions, devices, people, roles and places, and to draw out some otherwise implicit high-level goals:

The point of the exercise, for each student, is not just to master the individual tools but to participate in the construction of a co-ordinated web of activity that can result in a successful rescue, minimising danger to participants, and leaving traces, in some kinds of memory, that mean doing something like this again will not feel entirely new.

Goodyear and Carvalho (2019, p. 60)

Learning in networks can be rich and rewarding, but it is not straightforward to analyze or to promote. Patterns, experiences and outcomes can be very diverse. Learning networks can exist for a variety of purposes and not all of them are beneficial ([Castells, 2015](#)). As we have seen in recent years, digital networks are being used to spread misinformation and deepen mistrust. They can be used to organize peaceful protests but have also played a role in provoking and coordinating violence. Research needs to acknowledge that social learning in online networks can have a darker side. Researchers must be prepared to render more visible the multiplicity of ways in which networked learning unfolds, for good and ill.

For the purpose of this article, online learning refers to a form of distance education which depends on information and communication technologies for its design and delivery. Online learning assumes that students and faculty engage in instruction while separated spatially, temporally or both. This distinguishes online learning from more generic descriptors such as “e-learning” or “educational technology”. Unlike older forms of distance education developed prior to the digital age and dependent on analog technologies and physical media, online learning is defined by its networked digital nature. Whereas previous systems of distance education used forms of physical correspondence including the postal service, printed course materials, physical media such as analog videotape, and one-way broadcast media such as radio and television, current forms of online learning depends on digital materials, digital networks and the internet to foster two-way, asynchronous and synchronous interaction. This distinction has significant consequences for how online learning has grown, the forms of pedagogy it enables, and its effectiveness. This article focuses on online learning as a form of course and program delivery and credentialing, mostly in higher education settings. The organizing principle for what to include in the article centers on the role of online learning in increasing access to higher education and degree programs. The article also covers aspects of blended learning that combine face-to-face and online instruction where the goal is to increase access and improve pedagogy in higher education settings. Additionally, the recent massive shift to distance education made necessary by the COVID-19 pandemic is discussed. Finally, the article also touches on Massive Open Online Courses (MOOCs) in their role to increase access to higher education.

While online learning has been implemented in pre-college settings its impact and reach has been more limited due to the custodial functions of education setting designed for younger learners. Primary and secondary schools are accountable for the students enrolled in them including establishing physical proximity, taking attendance, reporting absences etc., so forms of distance education are less compatible with their overall function. This is not to say that online learning has not been important to primary and secondary students, especially in the transition to forms of distance education as a result of the COVID-19 pandemic, but the coordinated development of online learning has primarily occurred in post-secondary settings, where issues related to access, pedagogy, students, and faculty have shaped online education.

Development and growth of online learning

While beyond the scope of this article, it should be noted that the history of distance education dates back to the 1800s or earlier and modern distance methods and scholarship to the early 1900s. Pioneers such as Charles Wedemeyer utilized radio in the 1930s and 1940s; developed course books implemented for distance learning for military personnel during World War two; devised methods for combining correspondence education with television broadcasting and team-based instruction in the 1950s; and led the way with the use of satellite-based teaching methods in the 1960s. His work was highly influential on the founding of the Open University of the UK and shaped the work of later scholars such as Otto Peters, Börje Holmberg, and Michael Graham Moore (Diehl and Cano, 2019). Distance education has a very rich history that precedes and informs digital networked-based online learning.

Early examples of online learning in the US date back to 1970s and the first online courses and programs to the 1980s (Harasim, 2000). However, significant coordination of resources to support the development of online learning for the purpose of credentialing in the United States began in 1992 with the Alfred P. Sloan Foundation's Anytime, Anyplace Learning grant program (Sloan Foundation, N.D) for the development of what were then called “asynchronous learning networks.” This grant program distributed more than \$70 million to develop software, platforms, courses, programs, and sustaining infrastructure. An overarching goal was to ensure quality and develop a community of practitioners through convening grant recipients which ultimately led to the creation of the Online Learning Consortium (OLC, formerly the Sloan Consortium). This funding and the community the Sloan Foundation established has had a lasting legacy.

OLC also developed a series of reports documenting online learning enrollment growth in the US. Starting in 2002, the numbers of students taking at least one online course from a US higher education institution were estimated to exceed 1.4 million (Allen and Seaman, 2007). Those estimates continued to climb in the US and, by the 14th version of the report in 2017, by then relying on analyses from the National Center for Education Statistics' Integrated Postsecondary Education Data System (IPEDS), online enrollments stood at more than 6.3 million (Seaman et al., 2018). In 2019 the number of students enrolled in some or all online courses was nearly 7 million (National Center for Education Statistics, 2019). Tracking these figures after 2019 has become complicated by the COVID pandemic which resulted in a much more massive shift to forms of distance education.

The growth of online learning in the US has also been characterized as proceeding through four stages (Dziuban et al., 2016). These include the 1990s and internet propelled distance education; 2000–2007 categorized by the increasing use of Learning Management Systems or LMS (specialized software for digital course design and delivery); 2008–2012 characterized by the growth of Massive Open Online Courses—MOOCs; and the period since 2012 with growth of online higher education enrollments outpacing growth in traditional higher education enrollments. The standardization made possible during earlier periods, especially the development of the LMS, set the stage for ongoing growth in later years. Use of an LMS is nearly universal in higher education (Dahlstrom et al., 2014). This format of digitalization and networked delivery represents the advanced “industrialized learning” as described by Otto Peters (2007) in that it is characterized by professional planning, formalization, standardization, automation, division of work, and centralization.

Growth in online learning globally has been more difficult to estimate. According to a report by Qayyum and Zawacki-Richter, as of 2016, enrollments for a majority of countries providing distance and open education was 23,257,100 students (Qayyum and Zawacki-Richter, 2018). This included estimates for Australia, Brazil, Canada, China, Germany, India, Russia, South Africa, South Korea, Turkey, United Kingdom and the United States. This count included over 6.4 million enrollments in China and 4.6 million enrollments in India. However, these estimates are difficult to compare across countries. In the case of India, for example, more recent survey data from September 2018 from the Indian Ministry of Education shows 3,972,068 students enrolled in distance education in all higher education institutions (Ministry of Education of India, 2019). Qayyum and Zawacki-Richter comment on this challenge, noting that it is difficult to tally exact numbers of students enrolled in open and distance education as more precise enrollment counts reflect different populations (e.g., some students enrolled in self-paced courses in which they interact only with content rather than with instructors and other students). The key takeaway is that we lack reliable comparative higher education online enrollment estimates for most countries worldwide.

Regardless of exact comparative global enrollment data, observers acknowledge that online learning has been growing in most countries over the last two decades (Qayyum and Zawacki-Richter, 2018). The US, for example, has seen continuous, though varying, levels of online enrollment growth for 19 years from 2002 to 2020. The growth of online learning in the US bucks the downward trend in overall higher education in the US (Alan and Seaman, 2017). Similar patterns are apparent in other countries such as Brazil where distance education enrollment grew by 60% between 2009 and 2014 (Litto, 2018), though it should be noted that much of the infrastructure for distance learning is not fully digital in Brazil, especially outside large cities. Another example of online enrollment growth is China where the Ministry of Education reports (2016), online enrollments in higher education in China increased from 2.37 million to 6.45 million between 2004 and 2016. This steady growth in enrollments in countries worldwide reflects student demand for flexible options in the provision of higher education.

It should be noted that the growth of online learning did not occur without controversy, especially in the US. Early critics decried the end of education (Postman, 1992) and the rise of digital diploma mills (e.g., Noble, 1998). In reality, numerous for-profit higher education institutions were investigated by the US federal government. These investigations were prompted by concerns that many for-profit institutions were recipients of significant levels of federal funding, while comparatively underperforming. For example, in 2009, students at for-profit colleges received over \$4 billion in Pell Grants and more than \$20 billion in federal loans funded by the US Department of Education (United States GAO, 2010).

In the decade leading up to 2010, enrollment at for-profit colleges grew four fold, with US grants and loans accounting for over 90% of revenue at many institutions (Shireman, 2017). For-profit colleges accounted for more than a third of all student loan defaults, while these colleges enrolled just a little more than 10% of postsecondary students. For profit institutions have been accused of widespread fraud including distorting enrollment benefits, job placements and program offerings. Investigators concluded that, in many cases, these predatory practices left students with large debts and without college credentials. Investigations, subsequent regulation, and competition from non-profit providers ultimately resulted in lower enrollment growth among for profit institutions, though regulations have been relaxed in recent years (Ivory et al., 2018).

The COVID-19 pandemic and online learning enrollment growth

The pandemic forced institutions around the world to transition to distance education with much of that transition featuring some form of online remote instruction. Approximately 1.5 billion learners of all ages across the world were affected by school and university closures owing to the COVID-19 pandemic (UNESCO, 2020; UNICEF, 2020). This shift can be seen in enrollment figures in, for example, the US where total higher education enrollments were down (from 19.7 million to 19.1 million) but the number of students taking only online courses or some online courses, rose significantly. For Fall 2020, 44.7% of students took all of their courses online, 28.1% took some of their courses online, and 27.2% took no online courses. By way of contrast, for Fall 2019, those percentages were 17.3%, 19.3%, and 63.4% (National Center for Education Statistics, 2019, 2021). The pandemic thus has

a significant impact on the number of faculty teaching in digital distance environments, the number of students experiencing some form of digital distance education, and the number of support staff assisting with these tasks.

It has been noted that the form of digital distance education implemented in response to the global COVID-19 pandemic was not the same as the predominant form of online learning developed and implemented prior to the pandemic (Hodges et al., 2020). Many have referred to the pandemic-initiated shift as “emergency remote instruction” or similar terms to distinguish pandemic-response forms of distance learning from “traditional” online learning. The long term impact of the COVID-related shift to emergency remote instruction is still unclear, but a heightened institutional priority for online learning is evident from recent surveys (e.g., CHLOE 6, 2021).

Pedagogy of online learning

While online learning enables a broad range of approaches to teaching and learning, primary differences between older forms of distance education and online learning relate to assumptions about how people learn and what digital technologies enable. Online learning development roughly coincided with a relatively recent emphasis on social dimensions of learning in education research (e.g., Hmelo-Silver, 2003; Palincsar, 1998; Vygotsky, 1978) and away from strictly behavioral and cognitive paradigms. Analog forms of distance education were more likely to depend on independent learning and less on group learning, reflecting both technological constraints and views of how people learn. Correspondence methods of instruction necessarily relied heavily on student-content and student-teacher interactions. Online learning can more easily include greater student-student interaction, consistent with socio-cultural theories of learning, as well as student interactions with content and instructors in both asynchronous and synchronous digital formats. The use of digital networks and materials facilitates content delivery, interaction, learning activities, and assessments in ways that are also less costly and cumbersome than older analog methods. So, while two-way video conferencing, and the pedagogy it enables was possible before the digital networks such approaches were not scalable and thus not as ubiquitous as digital online learning has become.

The most frequently cited framework for online pedagogy in higher education, The Community of Inquiry (CoI) model (Garrison et al., 2001), reflects this socio-cultural focus on facilitating content and group interaction in the service of promoting learning. The CoI framework assumes that teaching and learning in higher education is not simply a matter of transferring knowledge from teacher to student, but falls within the conceptual domain of “collaborative constructivist” (Garrison, 2011) pedagogical approaches. This approach to online pedagogy prioritizes the facilitation of social as well as instructional and cognitive processes. Central to the CoI approach are modified replications of the discursive processes of science and other disciplinary communities’ epistemic practices that feature the engagement with arguments with reference to various forms of evidence valued by the discipline.

The assumptions that teaching and learning are inherently interactive, rather than based in transmission and reception of information, are reflected in the terms “community” and “inquiry” which describe online teaching and learning as both dialogic and active. This is not to say that all online learning follows this model, but to indicate that online learning does differ from older forms of distance education in light of its pedagogical potential. However, it should be noted that the concepts of conversation in distance learning, a goal of the community of inquiry model, was developed and described by earlier authors such as Holmberg (1983) who advocated for supportive and congenial dialog between students and instructors. The difference between Holmberg’s earlier conception of guided didactic instruction and the CoI model is in who does the talking, when, and under what conditions.

Holmberg and other earlier distance education scholars (e.g., Keegan, 1980) assumed that the dialog would occur between the instructor and individual students via mail, telephone or another medium (Diehl and Cato, 2019), whereas CoI-guided pedagogy articulates the benefits of instructor-facilitated discussion between students and their peers, enabled by digital asynchronous threaded discussion and other information and communication technologies that promote learner-to-learner dialog.

This distinction was highlighted by early researchers of online learning such as Gunawardena and McLissac (2003),

Asynchronous or time-delayed computer conferencing has shown the capability to network groups of learners over a period of time thereby challenging Keegan’s 1980 definition that learners need to be taught as individuals rather than in groups.

Gunawardena and McLissac (2003, p. 358).

The two-way nature of online group interaction is a defining feature of online learning environments that distinguish them from analog forms of distance education. The use of asynchronous threaded discussion with groups or the whole class, for example, allows educators to design activities that go beyond earlier correspondence methods. Many other digital learning technologies can be integrated into interactive online learning including simulations, video, multimedia-based asynchronous discussion, presentations, quizzes, tests and other educational technologies.

The adoption of learning management systems led to standardization (for better or worse) that enabled this asynchronous model to expand from course offerings to program offerings. Utilizing the LMS as a container for all course materials, assignments, assessments, and learning activities was foundational to this growth (as well as some constraints on creativity some have complained, e.g., Hill, 2014). Institutions found that there was a large market for this form of interactive asynchronous online learning

leading to college degrees. In turn, offering fully online programs brought online education to the mainstream of many academic departments, rather than residing off in separate distance education units.

Emergency remote instruction

As noted above, the global pandemic forced all institutions of higher education to move to distance education, largely based on digital networks. This move was conducted in days or weeks and the typical work of designing and building online courses, a process that can take months or longer, was not carried out. The resulting courses were quite different from those employing the interactive asynchronous pedagogical model described above. Most institutions relied much more heavily on synchronous modes of instruction through video conferencing and indicate that future online program offerings would likely rely more heavily on synchronous modes (CHLOE 6, 2021, p. 20). Prior to the pandemic fully synchronous online programs were somewhat rare. They may become more common given the prevalence of synchronous approaches across a broad swath of higher education as a result of emergency remote instruction.

A recent national study (Means and Neisler, 2021) examined student responses to pandemic-initiated emergency remote instruction and found a disconcerting set of issues. These included course satisfaction levels that were significantly lower after courses moved online, frequent technical issues, student difficulty staying motivated, a lack of immediate instructor feedback, and reduced collaboration between students. In addition, non-white students and poorer students encountered more challenges than did non-Hispanic White and more affluent students. Similar issues reflecting social inequities were found across the globe (Bozkurt et al., 2020).

Blended learning

Blended learning appears to be a straightforward concept that is a mix of online and classroom instruction. However, how online and classroom instruction are combined differs significantly across varying contexts. Some argue that blended learning implies a reduction of classroom seat time and that without this reduction the result is web-enhanced instruction (Mayadas et al., 2016). Others use the term hybrid instruction to refer to mixed online and classroom instruction (Graham, 2019). Attempts have been made to calculate precise levels of online and classroom instruction that qualify for the term blended including the definitions used by Allen and Seaman (2003) that blended learning combines at least 30% and not more than 79% online instruction with classroom instruction; below 30% is considered web-enhanced, 80% or more is considered fully online.

To reduce confusion a loose but parsimonious definition of blended learning has been proposed as the *strategic* combination of online and in-person learning (Graham, 2022), leaving aside ratios of online to classroom instruction and instead focusing on modality, media, and methods. Modality in this model refers to the physical setting (online or classroom); media are the digital and non-digital tools employed, and methods are the general and content specific pedagogies used.

The strategic combination of online and in-person instruction thus articulates how these “three M’s” are put to use in the service of containing or lowering cost, and or increasing access and student learning. The active ingredient in blended learning is not the modality, nor is it the media—it is the methods. For these reasons Graham advocates that researchers investigating blended learning clearly identify what is meant by blended learning and specify the physical and pedagogical dimensions of the blended model that is being researched.

Massive Open Online Courses (MOOCs)

Massive Open Online Courses (MOOCs) extend a longstanding goal of democratizing education through distance learning (Larreamendy-Joerns and Leinhardt, 2006). The first use of the term MOOC was applied to a course offered by George Siemens and Stephen Downes, *Connectivism and Connective Knowledge*, and was coined by Dave Cormier of Prince Edward Island University in 2008 (Cormier, 2008). The course was offered to both fee paying students of the University of Manitoba and to more than 2000 students who attended the course for free. This tied MOOCs to the “open” movement in higher education that focused on making education more accessible.

The course represented what came to be known as a cMOOC (Connectivist MOOC) to distinguish it from other large, open, online courses that developed several years later and would be known as xMOOCs. The original MOOCs were founded on the learning theory of Connectivism which highlights the power of networking with other individuals, learning from diverse perspectives, and the value in the reuse and remixing of resources. In essence, connectivism is the proposition that knowledge is dispersed across a network of connections, and learning is the ability to build and navigate those networks (Downes, 2011).

The term MOOC would later be applied to other free and open online courses that were founded on a different view of learning. These xMOOCs (or extended MOOCs) were typified by the Stanford course, *Introduction Into AI*, launched by Sebastian Thrun and Peter Norvig in 2011 (Pérez-Peña, 2012). The xMOOCs, frequently offered by elite institutions, enrolled tens and sometimes hundreds of thousands of students in online versions of courses taught by the same faculty who taught in the classroom. The courses

were organized around recorded video lectures, exercises, and quizzes, a significant departure from the more free-wheeling pedagogy of cMOOCs. Consortia of MOOC providers developed including Coursera, edX, and FutureLearn.

Given that enrollment in these kinds of courses was normally limited to the small numbers of students who were accepted into Ivy League and other highly selective (and expensive) colleges, offering them for free to anyone created tremendous interest. For a period of time after 2011 it was common to find discussions of technology in the media that predicted that MOOCs were either the future of, or end of higher education. The media touted MOOC developments, frequently conflating online learning itself with MOOCs.

The key difference between MOOCs and traditional online learning is in cost, credentialing and open enrollment. While offering learners free access to online courses, MOOC providers did not initially offer college credit or degrees to students. This would change for a small number of institutions in years to come, but with the initial hype (e.g., Pappano, 2012), “traditional” online learning, offered by thousands of colleges, was overshadowed by the MOOC phenomena. As noted elsewhere in this article, prior to the emergence of MOOCs many millions of students were already studying online and earning college degrees. Many of these students graduated from open enrollment institutions such as open universities and community colleges. But traditional online degrees were, of course, not free.

Two visions animated discussion of MOOCs—the original open access view that higher education, of the highest quality, could be provided to all learners, everywhere, via the internet for free (Koller, 2012) and, alternatively, a focus on a business model that would make MOOCs either sustainable or profitable. At this point the two visions continue to inform the development of MOOCs, but the awarding of credentials remains a sticking point. Students generally have to pay to access MOOCs in which they receive official credentials, either certificates of completion or, in some cases, complete degrees. The costs, it should be noted, are considerably lower than traditional college alternatives, but the open access policy has been removed for most MOOCs that award college degrees—students must qualify for admission to these programs. As of 2021 there were 72 MOOC based degree programs, 7 of which are at the undergraduate level (Ledwon, 2021) compared to thousands of traditional online degree programs, and tens of thousands of classroom-based degree programs. Most MOOC-based degrees are priced between \$10,000 and \$22,000, with some costing more (Ledwon, 2021).

Another persistent issue with MOOCs has to do with completion rates, which generally vary between 5% and 15% (Jordan, 2013). It has been long acknowledged that few students complete an entire MOOC course of study. Some argued that this was an indicator of quality or utility issues, with an early MOOC pioneer, Sebastian Thrun, stating that MOOCs were “a lousy product” (Chaffkin, 2013). Others argue that self-directed learners can gain as much as they need from a MOOC without necessarily completing an entire course and that specific learner demographics and motivations predict MOOC completion rates. Still others (e.g., Jordan, 2015) argue that MOOCs are not like traditional online courses and that comparisons are misguided. Course completion rates in MOOCs increase for those who pay for a certificate or degree. Additionally, completion rates fluctuate significantly according to course length, with courses of longer duration having lower completion rates. Dropout varies by when the course was first offered with more recent courses having higher completion rates (Jordan, 2015).

MOOCs, despite their initial hype, have clearly not replaced higher education, but neither have they been relegated to obscurity. In 2020, more than 950 universities offered more than 16,000 MOOCs to 180 million registered MOOC users, the largest growth in MOOC registrants in a single year ever (Shah, 2020).

Research and effectiveness of online and blended learning

Online learning has been the subject of thousands of studies examining how and under what conditions students learn most effectively in online settings, who learns, what content, and under what conditions. Several peer-reviewed scholarly journals are dedicated to understanding questions about learning in technology-mediated environments including online higher education. This includes journals such as the *International Review of Research in Open and Distributed Learning*, *The Internet and Higher Education*, and *Online Learning*, among many others.

In addition to the many individual studies presented in such journals, numerous meta-analytic reviews of online learning have also been undertaken on the effectiveness of distance education, online and blended learning. This section includes more recent reviews of distance education as the meta-analyses that cover this topic include online learning by the early years of the 21st century.

The emerging answer about online learning effectiveness is that there is no significant difference between online and classroom learning. For example, in 2004 a meta-analysis by Bernard and his colleagues (Bernard et al., 2004) included an analysis of achievement, attitude, and retention outcomes across 232 studies. Results indicated effect sizes of essentially zero on all three measures indicating no significant differences between online and classroom environments studied. A year later Zhao and his colleagues reviewed 51 studies examining 99 outcomes (Zhao et al., 2005) and found no significant difference between distance education and face-to-face education. The following year Tallent-Runnels and her colleagues (Tallent-Runnels et al., 2006) conducted a narrative (rather than meta-analytic) review focusing on online learning specifically. In this study the authors reported that asynchronous communication appeared to support in-depth communication (equivalent to traditional classes), that students liked to move at their own pace; that learning outcomes appeared to be the same as in traditional courses, and that students with prior training in computers were more satisfied with online courses.

Each of the meta-analyses reports wide variability within the online learning literature with some studies reporting outcomes that favor classroom or traditional settings and some studies favoring online or distance settings. It is rarely the case that the

individual studies report no significant difference between distance and face-to-face instruction. However, the differences fade when the studies are considered in the aggregate. Zhao et al. (2005) took note of this and asked why some studies find distance education students have better achievement than their counterparts in traditional classrooms and some studies find the opposite. What factors account for the differences? The authors investigated 51 of the most rigorous studies of online and distance education and examined the many factors that might account for differences. While concluding, as others had earlier, that overall there were no significant differences in the aggregate, they also found that many more studies reported distance/online learning to be superior on outcome measures. About two-thirds of studies favored distance/online learning and one-third favored classroom instruction. The authors also found that more recent studies favored distance/online learning, as did those in which there were higher levels interaction in the online condition.

In 2009 with the large growth of online learning, the US Department of Education sponsored what was to be a gold-standard, highly controlled study of web-based distance education. The overarching goal of the study (Means et al., 2010) was to provide policymakers, administrators, and educators with direction about how to implement online learning for K–12 education and teacher preparation. However, very few studies of k-12 populations existed and the purposes of the research had to expand to include higher education studies. Despite finding more than a thousand such studies, as with the Zhao study, a limited number of these met rigorous standards for quality that would allow inclusion in the meta-analysis. This study differed from previous meta-analyses in that it focused solely on web-based online learning, exclusively focused on objective measures of learning, and included only studies with random assignment or controlled quasi-experimental designs. Of the 45 studies that met inclusion criteria the authors calculated effects of online instruction for 50 contrasts or comparisons with classroom instruction.

The meta-analysis concluded that students in online conditions performed modestly better, on average, than those learning the same material through traditional face-to-face instruction (Means et al., 2010). In addition to this general finding, the authors also found that combining online and face-to-face elements through blended or hybrid instruction was even more effective, compared to purely face-to-face instruction, than was purely online instruction without some elements of blended or hybrid instruction. Further, the authors concluded that online instruction that was collaborative or instructor-directed was more effective than in conditions where online learners worked independently without much interaction with instructors or peers.

The authors warn that despite what might be construed as strong endorsement for blended learning, the studies reviewed and analyzed in this meta-analysis do not demonstrate that online learning is superior as a medium of instruction per se. Studies that showed better outcomes with blended learning had differences in the online and classroom conditions with regard to time, curriculum, and pedagogy. It was the combination of these elements, which likely included additional learning time, different content, and additional opportunities for collaboration, that resulted in better outcomes rather than some feature of the online medium (Means et al., 2010). The final conclusion was that studies contrasting blends of online and face-to-face instruction with conventional face-to-face classes, find the former to be more effective, justifying resources required to design and implement blended approaches. On its own, online learning is as effective as classroom instruction, that is, not significantly different from traditional instruction in terms of learning outcomes reported in the literature.

In summarizing the meta-analytic literature on the effectiveness of distance, online, and blended instruction compared to classroom instruction, Bernard and his colleagues indicated that the two can be equivalent in terms of student achievement (Bernard et al., 2019). These authors further argue that a small number of variables seem to matter in making a difference between forms of distance education and classroom instruction. Higher levels of interaction, whether occurring between students, students and instructors, or students and content, lead to better outcomes for distanced, online, and blended instruction, relative to classroom instruction. Further, as found by Means et al. (2010), Bernard found that blended learning has a more pronounced effect size in terms of student achievement than does pure online learning, when compared to classroom instruction. Finally, these authors argue that intentional design provides additional advantages with regard to student-student or collaborative interaction above and beyond the mere presence of collaborative opportunities made possible by collaborative tools or affordances (Bernard et al., 2019). Enabling the learning benefits associated with collaborative learning is enhanced through intentional design.

The future of online learning research

Consensus exists that additional studies comparing online and classroom instruction are not needed and that the field will only move forward if new research comparing different interventions in online and blended environments is completed (Clark, 2000; Cook, 2009; Bernard et al., 2019). According to Bernard et al. (2019) what is needed are more primary research studies that compare one distance education, online learning, or blended learning condition to another, rather than new studies comparing these to classroom instruction. Rigorous studies that are grounded in theory and which focus on different instructional methods, rather than modality, represent the most productive path forward for the field. Altering the target of research to “important questions of design, interaction, student and teacher involvement, feedback, etc is critical ...” (Bernard et al., 2019, p. 102).

Glossary

Gifs A *gif* is an image, or series of images for an animated gif, saved in the graphics interchange format. This format compresses files to allow for the quick sending and sharing of images. Gifs are commonly used to send, post, or share images (or short video clips) via various social media, messaging or texting platforms, and emailing. Images of key moments from pop culture, movies, or tv shows are often turned into gifs and used to express humor or represent the sharer's emotional state or response when posting online. For example, after seeing a colleague's tweet about a recent accomplishment at work, a friend reply by posting a gif of an audience applauding or characters from a well-known tv show cheering

Subreddit A *subreddit* is one of many distinct, theme-based discussion forums hosted on Reddit's platform ([reddit.com](https://www.reddit.com)), typically denoted by a "r/" in the title of the forum. For example, "r/Teachers" is a discussion forum on Reddit organized and moderated by teachers, providing a space for teachers to ask questions and share stories related to their profession

Introduction to social media and learning

Approximately half the world's population is now using social media (Statista, 2021a,b), a trend that accelerated during the COVID-19 pandemic (Koeze and Popper, 2020). Human learning has moved increasingly online as individuals now have more choices about when, where, how and with whom they learn (Greenhow et al., 2020a,b; Greenhow and Lewin, 2021). Researchers in various disciplines have documented the rising use of social media for educational purposes (Rehm et al., 2019). Indeed, scholars around the world have theorized and examined social media's varied and complex impacts on student and teacher learning within and out of schooling (Greenhow et al., 2009). For instance, social media such as social networking sites and microblogging can expand learning opportunities (Manca and Ranieri, 2013, 2016); enhance students' well-being, identity, and literacies (Greenhow et al., 2011; Greenhow and

Gleason, 2012; Greenhow and Robelia, 2009a,b; Marich et al., 2021); and deepen student–teacher relations (Gao et al., 2012). The integration of social media in education can foster students’ active learning, collaboration skills and connections with communities beyond the classroom (Greenhow et al., 2020a,b, 2019a). Social media are also impacting the learning and communication of teacher-scholars, including how scholarship is reviewed, disseminated or taken up by various audiences (e.g., Greenhow et al., 2017; Greenhow and Gleason, 2014; Greenhow et al., 2019b,c; Li and Greenhow, 2015).

However, social media also pose ethical challenges and risks; marketing efforts present social media algorithms to the public as if they are objective and value-neutral tools. In essence, algorithms reflect the values of their builders who hold positions of power (Hrastinski et al., 2019). Whenever people create algorithms, they also create a set of data that represents society’s historical and systemic biases, which ultimately transform into algorithmic bias (Krutka et al., 2019a,b); we can see various gender and racial biases in different social media platforms (Stahl and Wright, 2018). Thus, ethical issues such as privacy, surveillance, autonomy, bias, and discrimination must be considered when social media are implicated in learning, and educators will face different ethical concerns and challenges depending on their students’ grade and age of development (Akgun and Greenhow, 2021; Greenhow et al., 2016).

Given the possibilities and perils of social media and learning today, in this article we draw from published relevant research and literature reviews of over 15 years of scholarship to provide a brief overview of the state-of-the-field. Although critical engagement with all relevant topics related to social media and learning is outside the scope of this article, we highlight three topics on the cutting edge of research and practice: (1) *literacies* for a changing world; (2) *civic engagement* on social media; and (3) *professional learning networks* spanning social media.

Overall, our goal is to catalyze and contribute to global conversations about the diverse purposes, practices, and policies of our educational future, spanning its formal-informal learning continuum and with the internet and social media playing a pivotal role (Greenhow and Lewin, 2016). The COVID-19 global health emergency upended educational systems as countries were forced to rapidly switch to online, blended, and remote forms of learning. Nations watched as a temporary solution to the problem of delivering education during the COVID-19 pandemic played out on the internet: “The primary objective was to quickly provide temporary, reliable access to instruction and support during a crisis, not to re-create a robust educational ecosystem” (Hodges et al., 2020, para. 13). As the world moves forward, beyond the pandemic, we have the opportunity to rethink and restructure educational ecosystems and advocate for visionary scholarship. This article is intended as a step in this direction.

Social media and learning

Definitions and brief history

In 2019, Merriam-Webster defined *social media* as “forms of electronic communication (such as websites for social networking and microblogging) through which users create online communities to share information, ideas, personal messages, and other content (such as videos).” Hallmarks of social media are that they are *Web 2.0 Internet-based* applications that feature *user-generated content*, *profiles* for the site or app created by users, and the development of *online social networks* by connecting a user’s profile with those of other individuals or groups within the system (Obar and Wildman, 2015). This last hallmark feature: the facilitation and development of online social networks is more prominent in some social media types than others, such as in social network sites like Facebook which spotlight people’s list of connections and feature the ability to view and traverse the connections of others. Some scholars have originated terms like *educational social networking* to characterize the combination of the networking features on social media with education-based goals or content (Galvin and Greenhow, 2020). Educational social networking occurs when teachers, students, or others gain or create knowledge together through social networking activities (e.g., teachers using #EdChat to ask questions and gain support from peers (Greenhow et al., 2021)). Next, we identify central themes and conceptualizations related to social media in education.

Although social media did not become mainstream until the mid 2000s, scholars generally agree that the first social media site arose in 1997 with the creation of *Sixdegrees.com*, which allowed users to: (1) create profiles, (2) list a set of other users with whom they shared a connection, and (3) view and traverse others’ connections (Boyd and Ellison, 2007). Although these features existed in various forms independently, *Sixdegrees.com* was the first to combine them (Boyd and Ellison, 2007). The late 1990s and early 2000s saw the rise of blogging, on platforms such as Blogger and LiveJournal, which featured the composition and maintenance of multimedia web articles posted in reverse chronological order and often having images and links to other websites. Around this same time, social media called wikis, used for collaborative web-authoring on platforms such as wikispaces, gained in popularity. Prior to 2001 wikis were virtually unknown outside closed circles of computer programmers. In the early 2000s Friendster, considered one of the first social network sites, was growing in prominence, mostly in Asia. From these beginnings there are now thousands of platforms across various types of social media. Experts generally agree that social media include 13 types with some of the most prominent types being: blogs (e.g., Blogger), wikis (e.g., Wikipedia), social network sites (e.g., Facebook), microblogs (e.g., Twitter), photo-sharing services (e.g., Instagram and Pinterest), video-sharing services (e.g., YouTube), products/services review (e.g., Yelp), social bookmarking and social gaming (Obar and Wildman, 2015). Furthermore, mobile social media are social media on mobile devices such as smartphones and tablets and typically incorporate the location of the users. According to global social media statistics reported in July 2021, approximately 57% of the world’s population use social media or 4.48 billion users, an increase of 13% over the past year (DataReportal, 2021). Almost all users (99.0%) are mobile users, spending approximately 2.5 h each day on their chosen social media. Across the globe, the 16 social media with the most active monthly users, listed in

order are: Facebook (FB), YouTube, WhatsApp, Instagram, FB Messenger, WeChat, TikTok, QQ, Douyin, Telegram, Sina Weibo, Snapchat, Kuaishou, Pinterest, Reddit, Twitter. Interestingly, of these top social media, 4 are owned by Facebook: Facebook, FB Messenger, WhatsApp, and Instagram (DataReportal, 2021). Many people are mobile, multi-platform social media users. Among young people (ages 18–29) in the United States, for instance, the most used social media platforms (as of February 2021) were YouTube (95%), Instagram (71%), Facebook (70%), Snapchat (65%), Tik Tok (48%) and Twitter (42%) (Pew Research Center, 2021).

Themes in the research on social media and learning

Participatory, constructivist and social learning frameworks have been some of the most widely used frameworks to study social media and learning (Greenhow et al., 2020a,b; Macia and Garcia, 2016). Other commonly used theoretical frameworks are Professional Learning Networks (PLNs) and Communities of Practice (CoP) theories. Recent literature reviews reveal that a large proportion of studies dealing with social media and learning address the continuum of formal-informal learning contexts (Greenhow and Lewin, 2016) and the rise of spontaneous, agentic learning possibilities for changing contexts/times (Greenhow et al., 2021, 2020a,b; Manca and Ranieri, 2016).

Existing published literature reviews related to social media in education have focused mainly on learning or teaching with a particular social media type (e.g., social network sites) (Greenhow and Askari, 2017; Rodríguez-Hoyos et al., 2015) or platform, most commonly Facebook (Aydin, 2012; Hew, 2011; Manca and Ranieri, 2013, 2016; Wilson et al., 2012) or Twitter (Alias et al., 2013; Gao et al., 2012; Tang and Hew, 2017). Most of the studies in these reviews focus on the perceptions and experiences of college students (Aydin, 2012; Manca and Ranieri, 2013) and higher education faculty (Forkosh-Baruch and Hershovitz, 2012). Moreover, the benefits of appropriating social media into teaching and learning contexts are contested in the research literature. Some studies on the integration of social network sites like Facebook in higher education suggest their affordances for collaboration, information and resource sharing (Maxman and Usluel, 2010); encouraging participation and critical thinking (Ajjan and Hartshorne, 2008; Mason and Rennie, 2006); and increased peer support and communication about course content and assessment (DiVall and Kirwin, 2012). Others warn against exploiting social media for learning because of its potentially negative impact on student outcomes such as college GPA (Junco and Cotton, 2013; Kirschner and Karpinski, 2010) or ethical dilemmas that must be understood and navigated by students and teachers (Krutka et al., 2019a,b).

In a recent literature review of over a decade of research on social media in education (i.e., studies published in 2004–2017) (Greenhow et al., 2020a,b) we focused on teaching and learning with social media in elementary and secondary level education—among learners ages 5–18. We found that this topic has been studied in 17 different countries and that such studies had been increasing in number in the last 5–7 years (Greenhow et al., 2020a,b; Rehm et al., 2019). Facebook and Twitter were the most studied platforms, with many articles covering teachers' use of social media for informal professional development (PD) (i.e., PD not structured or required by the teacher's school or district) (Greenhow et al., 2020a,b). Classroom-based studies indicated social media's potential to improve student learning experiences, such as through increased critical thinking, active learning, and engagement. However, most research did not address implementations tied to student outcomes (Greenhow et al., 2020a,b, 2019a). Challenges to teaching with social media included navigating the complications of maintaining teacher–student interactions on social media and the balance between professional boundaries and being accessible to and supportive of students. Through using social media for informal PD, teachers were able to self-direct their learning, build networks and communities that may not be available in face-to-face settings, and make connections to others that satisfied their emotional needs and alleviate isolation (Greenhow et al., 2020a,b).

Next, we highlight three topics on the cutting edge of research and practice in relation to social media: (1) *literacies* for a changing world; (2) *civic engagement* on social media; and (3) *professional learning networks* spanning social media. Each topical section begins with an overview or introduction to the topic, its significance, and what we currently know from contemporary educational research. The section continues with the affordances and constraints of social media related to that topic (i.e., literacies, civic engagement, professional learning) and concludes with emerging issues in the topic and why they are important to forward-looking research and/or practice.

Literacies for a changing world

In today's 21st-century society, people often take on the role of *creator* or *author* through various online forms and modalities. Beyond putting pen to paper, individuals go online to design and share content made of combinations of text, images, videos, and audio recordings. On social media billions of users compose content ("Most used social media 2021," 2021), especially young people (Perrin and Anderson, 2019). The wide range of skills—or *literacies* (Lankshear and Knobel, 2008)—now commonly utilized in digital spaces to create and share content suggests that conceptions of literacy are rapidly evolving alongside technological advancements.

Unsurprisingly, digital literacies, such as those used on social media, have become some of the most in-demand skills for workplace success (Adams Becker et al., 2017; Oberländer et al., 2020). According to Adams Becker et al. (2017, p. 6), university graduates surveyed indicated the largest digital literacy skills gap they faced was the ability to create, produce, and develop content with digital tools. Furthermore, the researchers found a positive correlation between digital literacy training and occupational success.

Employers' expectations about the digital literacy skills of their workers continue to increase, yet potential applicants remain under-prepared (Murray and Perez, 2014; Oberländer et al., 2020; Raish and Rimland, 2016). More attention to how social media function as spaces for important literacy practices and how these are integrated into formal education is needed.

Features and descriptions of social media literacies

As described above (see **Definitions and brief history** section), social media platforms have distinct features that distinguish them from other online spaces, including the opportunity to create an individual profile, to establish and view others' network connections (e.g., friend list), and to view and participate in a stream of user-generated content (e.g., Instagram feed) (Ellison and Boyd, 2013, p. 158). These features translate to digital literacy skills by requiring users to learn and understand how to engage with different platforms' unique elements. For example, on Facebook—the most-used social media platform globally as of July 2021 (“Most used social media 2021,” 2021)—users design a profile page, where personal information, pictures, and media can be posted. They can also create story posts: short video clips users can post for others to view for 24 h. Users can find and add Facebook Friends, creating lists of people that can view various aspects of their profile and certain posts. Posts can be shared with their entire Friend network (i.e., standard post on one's profile); they can be shared publicly but toward a particular friend (i.e., posting on a friend's profile or tagging them personally), or they can be shared privately to an individual through Facebook's direct messaging feature. Individuals can reply with text and images (e.g., memes, gifs) or react to posts by clicking a “like,” “love,” “laughing,” “amazed,” or “angry” emoji. The intricacies of how communication and interaction take place across platforms can be surprisingly complex and require knowledge not only of how to access and implement platform features but also of social norms practiced on that platform. The following section elaborates further how these social media practices are understood as a form of digital literacy.

Social media composition as literacy

The current paradigm in literacy research, New Literacy Studies (NLS), is a large umbrella topic that defines literacy as sociocultural practices (i.e., the social and cultural context of literacy use define its meaning and significance). In this way, literacies are both expressions of identity and social practices. Literacy happens differently depending on one's audience and how the author/composer seeks to present themselves to that audience (e.g., Gee, 2008). For instance, the literacies students use to present certain identities when interacting with their instructors will be different from the literacies that students choose to use when presenting different identities during interactions with their friends.

Within NLS, the *new literacies studies* movement pluralizes literacies in order to represent the inclusion of proficiencies beyond reading and writing as types of literacy practices (e.g., media literacy, information literacy, digital literacy). Digital literacies are one example of proficiencies intended to represent all proficiencies necessary for effective use of any digital tools or resources (e.g., social media). Understanding these specific proficiencies continues to challenge researchers as technology continually develops and, therefore, the savvy needed to utilize digital affordances constantly evolves (e.g., Pangrazio, 2016). It is common for social media, for example, to rise or fall in popularity quickly, meaning the literacies users need to navigate new or changing platforms must be developed just as rapidly.

Affordances and constraints of social media as spaces for literacies

Social media offer various affordances and constraints as spaces for literacies. This section highlights two of the most significant and unique aspects of social media that can function as both affordances and constraints: (1) social media as spaces for identity exploration and self-expression, and (2) social media as a connection to large, interactive audiences.

Social media facilitate identity exploration and self-expression

One important affordance of social media is their ability to facilitate creative freedom and opportunities for users to explore and express new identities. For example, Gleason (2018) followed three youth as they explored, developed, refined, and solidified their own unique feminist identities on Twitter over the course of multiple years. The participants created personalized tweeting styles, voices, and interests that reflected their beliefs. Relatedly, in Wargo's (2017, pp. 575–576) case study of LGBTQ youth, he found the participants' created content to express who they were “on their own terms,” giving them the power to control the narrative communicated to others about themselves and to “be known differently.” Social media welcomes and empowers all types of individuals to be themselves and is designed to prompt personal expression through features that allow users to customize their profile and content presentations (e.g., pictures, music, videos, other formatting features) (Gallant et al., 2007).

Although social media's emphasis on creativity affords self-expression and identity development that is often valued in formal educational settings, its openness to creative freedom can also act as a constraint that limits how effectively it can be used in school. Research suggests that youth seek out social media as outlets for their passions and interests that are not accepted elsewhere, such as in school (e.g., Bickerstaff, 2012; Greenhow et al., 2015; Padgett and Curwood, 2016). The separation of social media from school settings, which are often associated with restrictive standards and expectations, seems to add to social media's appeal. Attempts to bring social media literacies into the classroom can be problematic and confusing to students who may want to keep some of their online identities or practices private (e.g., Chromey et al., 2016; Whitney, 2011) or who are unsure how to navigate a traditionally out-of-school space within formal education structures (e.g., Galvin and Greenhow, 2019; Lantz-Andersson et al., 2013).

Social media offer connections to large, interactive audiences

Another important affordance of social media is the access platforms offer to unique audiences that are often larger and more interactive than can be found in offline settings. In school, students are taught to think of their audience as a receptive reader: someone who will read what they write but not necessarily someone who will respond and interact with them in a timely manner. Lammers and Marsh (2015) found that teen Laura used social media to share her fanfiction specifically because she sought a social audience—peers who genuinely appreciated her work and communicated with her about it. While on social media, instead of relying on social connections to those only in close geographical proximity, “people now exist as networked individuals, able to call on a large and diverse set of [online] connections when they really need them” (Humphreys, 2016, p. 161). This increase in social capital is especially valued by youth for supporting their relationships with peers (Ellison et al., 2007; Greenhow et al., 2011).

Importantly, it is not just the interactivity nor larger size of a networked audience that makes it an affordance for social media users, it is the perceived authenticity of users’ connections with their audience (e.g., Padgett and Curwood, 2016). Having an authentic audience can be motivating and inspiring; however, this type of audience can also pose challenges or even dangers to online content creators. Important restrictions schools and teachers place on social media access or allowed practices to protect students can limit the achievable audience authenticity when using social media in the classroom, reducing student interest or engagement (e.g., Galvin and Greenhow, 2019). Furthermore, users’ obsessions over audience feedback and positive reinforcement can become an addition, negatively impact their self-esteem and self-worth (e.g., Balakrishnan and Griffiths, 2017; Burrow and Rainone, 2017). While the connection to audiences available on social media can be enriching and exciting, learning to understand and mitigate risks related to sharing content online must be a priority.

Emerging issues in social media literacies

Social media literacies are ubiquitous for many people worldwide yet, as described in this section, questions and challenges remain. Considering how digital literacies used on social media may be effectively integrated into classroom learning continues to be an important issue. Bridging in-school literacies with out-of-school literacies does not mean a rejection of traditionally academic writing nor a new expectation of writing Facebook posts during class. Rather it is a notion meant to inspire a new open-mindedness and a reevaluation of which literacies are privileged in schools compared to the literacies that are most valuable and meaningful to students. Now that students are spending significant time developing literacy skills online (Anderson and Jiang, 2018), potentially more than they are during school, and the future of our 21-century job market is founded on writing and other digital literacies (Adams Becker et al., 2016), social media have emerged as spaces integral to our daily literacy practices. This raises concerns for user safety, and calls for education that prepares users to think critically about audience and the interactive nature of social media in general (Krutka et al., 2019b). To continue accessing and elevating the affordances of social media, users must know how to engage in online spaces as safe community members, not just as content creators. In the next section, we elaborate on one aspect of how to be community members on social media: civic learning and civic engagement.

Civic learning with social media

Civic education, or the teaching of young people to be informed and active citizens, must improve if it is to prepare young people to inherit democracy (EAD, 2021; Luntz, 2020). Civic education in the United States, for instance, is often misaligned with established best teaching practices or the ways in which students participate in civic life (Chapman and Greenhow, 2021). While the need for improved civic education is now being emphasized globally in response to various world events, few studies have explored how social media functions in the civic sphere and how to support young people’s civic engagement via social media. Nearly half of people aged 18–29, for instance, used social media for civic engagement in the 2020 U.S. election cycle, by creating their own civic content, describing their experiences as members of society, or by designing and sharing media (CIRCLE, 2021). This trend has prompted scholars to theorize the ways in which young people are engaging in civic life via social media, as well as how social media can support civic learning.

Civic engagement on social media

While the types of media used to create and distribute information, to engage in boycotts or #hashtag movements, or to connect with other citizens is varied, the use of social media for civic education is understudied in the educational research literature (Chapman, 2019). For example, people took to Twitter to connect to, participate in, or critique the demonstrations, protests, and uprisings known as the Arab Spring, the Occupy Wall Street movement, the Black Lives Matter movement, the #MeToo movement, and the #NeverAgain movement. In 2011 in Egypt, young people used Twitter to protest and organize activists who brought down the regime of President Hosni Mubarak (Pew, 2012). Also in 2011, young adults used Twitter to propel a suggestion in a magazine into the Occupy Wall Street movement (Preston, 2011). American high school students (ages 14–18) who survived the school shooting in Parkland, Florida in February 2018 began the #NeverAgain movement, which prompted the March for Our Lives in cities across the United States (Shear, 2018). Such hashtag movements can also be longstanding: while the #BlackLivesMatter hashtag first emerged in 2013 in response to the murder of the African American man, Trayvon Martin, its use and reach

have increased dramatically since the murder of another African American man, George Floyd, in 2020, with the hashtag being tagged on over 25 million posts and garnering 444 billion likes (Wirtschafter, 2021). Today, Twitter is actively used by young people as both a method and a tool of civic engagement.

Understanding civic learning and engagement on social media

The goals of civic education

Civic education, and the preparation of young people to be active citizens, has been an aspect of public education in many countries for centuries (Mann, 1842; Krutka, 2014). Recently, the goals of civic education in the United States were outlined in a report entitled: "The Republic is (Still) at Risk," (Levine and Kawashima-Ginsberg, 2017). The report outlined ten aspects of US civic education that should be included in order to prepare students to be active, engaged, participatory citizens:

- Classroom instruction in civics, government, history, law, economics, and geography
- Discussion of current events
- Service learning
- Extracurricular activities
- Student participation in school governance
- Simulations of democratic processes and procedures
- News media literacy
- Action civics
- Social-emotional learning (SEL)
- School climate reform

How civics is frequently taught

In spite of calls for these ten components of American civic education, and research which supports the importance of their inclusion for effective civic education, only two of these approaches (knowledge transmission and discussion) are consistently incorporated (EAD, 2021; Hanson et al., 2018). Further, the content taught by US civics teachers is narrow; most civic education focuses only on the American form of government or wars and military heroes (Lopez et al., 2006). Only 11% of students surveyed reported that civics classroom topics included discussion of contemporary problems or issues for the US today (Lopez et al., 2006). While in the last decade, some states have required discussion as part of their civics requirements, it is concerning that most civic education is focused on content acquisition rather than on developing civic skills or dispositions (Hanson et al., 2018).

What is missing from civic education today?

Despite the increased use of social media for civic engagement among young people, traditional forms of civic engagement, such as writing letters to newspapers and elected officials or joining a political party, are emphasized in formal civics education (Torney-Purta et al., 2001). While young people frequently do not engage via these approaches, they remain the focus of civic education, often relying on ineffective methods focused on skills that are infrequently used among youth (Hanson et al., 2018; Torney-Purta et al., 2001). Social media features that can facilitate new forms of civic engagement for young people are currently underexplored and undertheorized. The use of social media in civic education allows learners to construct their own knowledge in social environments that are realistic, addresses several of the areas where current civic education practices fall short of research-supported pedagogies, and taps into ways in which youth prefer to engage in civic life (Chapman, 2019; Hanson et al., 2018; Robelia et al., 2011; Torney-Purta et al., 2001).

Affordances and constraints of social media for civic engagement

Social media has numerous affordances for the development of civic literacy. In particular, social media allows users to create and share their own content; the inherently participatory nature of social media provides users with an opportunity for civic engagement (Chapman, 2019; Chapman and Greenhow, 2019; Roberson, 2018). When used in educational settings, social media can increase students' participation and engagement in content area learning (Ebner et al., 2010; Gao et al., 2012). Junco et al. (2011) further found that the use of Twitter in class enabled students who would not normally participate, to do so.

Gao et al. (2012) found that classes which used Twitter were able to connect with Twitter users beyond the classroom, who brought lived experiences to learning and added to the authenticity of the learning experience; students reported being excited by these interactions (Gao et al., 2012). Interacting with people and groups outside the classroom can facilitate students' application of in-school learning to the real world, and research has also shown that students who use Twitter are more likely to become involved in the wider community (Rinaldo et al., 2011). Students learning about civics can find people on social media they would not otherwise interact with, including government representatives, student activists, and leaders of social movements.

Another affordance of social media is that it can expand the pool of learners and instructors, as well as the roles that they play. Tweeting about topics that are brought up in class promotes interaction between students, the instructor and other Twitter users (Gao et al., 2012). While traditionally instructors are suppliers (or sometimes producers) of knowledge, and students are consumers of knowledge, using social media allows those roles to become more fluid. Students can consume information from a variety of

sources; they can also co-produce and curate knowledge in ways that are not usually seen in traditional classrooms (Gao et al., 2012) but which can promote civic engagement. When students were able to co-create and contribute information and materials, they were more likely to be active students (Dunlap and Lowenthal, 2010; Perifanou, 2009).

There are also constraints to using social media to develop civic literacy which need to be addressed. First, some teachers perceive that students do not need to learn about technology in order to use it; this has been shown to be inaccurate (Brown and Czerniewicz, 2010; Chapman, 2019). Secondly, in addition to teaching students how to use social media, teachers must teach *about* social media, particularly the ways in which users of it can be manipulated or subject to misinformation (Chapman and Greenhow, 2021).

Emerging issues in education

To address these constraints, we need to understand how teachers can better support students' civic participation via social media through civic education. Students need to learn how to use social media for civic participation and how social media platforms work. The very ways in which social media platforms are designed can create echo chambers, spread misinformation and manipulate users (Chapman and Greenhow, 2021). The future of civics teaching with social media must include preparing students to combat these more nefarious aspects of these platforms. Only then will students be prepared to use the affordances of social media for civic participation.

Networked professional learning spanning social media

As the field of education continually changes and evolves through various reform movements and innovations, education professionals must adapt in kind. This necessitates ongoing professional learning among educators that cannot be fully met by formal education (e.g., teacher preparation program, graduate programs in education) or traditional professional development offerings (e.g., district workshops and in-service days). Increasingly, educators have turned to digital technologies to connect with each other, gain knowledge and secure resources needed to address challenges in their professional contexts. Social media platforms, in particular, have created new opportunities for educators' ongoing professional learning (Trust and Prestridge, 2021). However, the number of social media platforms continues to increase, leaving educators to navigate an increasingly complex landscape of professional learning.

Definitions

Networked learning can be understood as a shift in emphasis from purely internal aspects of learning from an educational psychology perspective, to including external factors (e.g., social influences, environment) made possible through the internet (Natriello, 2016). In other words, the internet has allowed people to build and sustain networks of interpersonal connections that "increasingly and more obviously contribute to the learning opportunities of individuals in postindustrial societies" (Natriello, 2016, p. 337). Of particular interest in this article is *networked professional learning*—specifically, educators' learning supported by the novel social and environmental conditions created by social media.

Understanding networked professional learning on social media

Scholars have framed networked professional learning in numerous ways, including broad, general conceptions such as "grassroots professional development" (Forte et al., 2012) and "open online learning" (Haythornthwaite et al., 2018). Others have emphasized learning theories of learning, such as by focusing on knowledge acquisition through socialized knowledge communities (Hu et al., 2018) or networks of practice (Brown and Duguid, 2017; Ranieri et al., 2012).

The framing of networked professional learning is important because each framework emphasizes different aspects (Staudt Willet et al., 2017) of what is occurring when educators connect with each other on social media for professional purposes. Here, we consider four perspectives on networked professional learning that offer distinct views: putting the social media platform at the center, placing the individual learner at the center, centering the group, and taking a system-wide view.

The *affinity spaces* framework focuses attention on the social media platform. Affinity spaces can be understood as locations—including virtual ones—where shared interests bring people together (Gee, 2004). The common affinity is reflected in the content of the space and in how users of the space interact with each other. Affinity spaces are a general and neutral approach to understanding social media, and this framework has been used by a broad range of social media researchers. For instance, affinity spaces are a way of understanding the more than 900 distinct education-related Twitter hashtags (Participate Inc., 2019), which include #Edchat for broad education conversation (Staudt Willet, 2019; Xing and Gao, 2018), #michED for educational concerns in the US state of Michigan (Greenhalgh et al., 2020), #NGSSchat for discussions of science teaching standards (Rosenberg et al., 2020), and #SocialMediaSyllabus and #MarginalSyllabus for collaboratively developing teaching syllabi (Greenhow et al., 2019b). Affinity spaces have also been used to describe the distinct, teaching-related discussion forums (i.e., subreddits) comprising the Reddit Education Network (Carpenter and Staudt Willet, 2021; Staudt Willet and Carpenter, 2020, 2021), such as r/Teachers, r/education, and r/teachingresources.

In contrast to a spatial frame, *professional learning networks* (PLN) focus attention on the individual learner. PLNs can be understood as a support system of interconnected tools, resources, people, and spaces that an educator builds around themselves to help improve their professional practice (Krutka et al., 2017; Trust et al., 2016; Trust and Prestridge, 2021). An educator's PLN can span both online and local contexts. For instance, a new teacher may consider their PLN to include peer and mentor teachers in the school where they teach, a professional learning community organized by the school district for teachers of the same subject, a major professor from their teacher preparation program, a Facebook group for teachers, and a handful of Twitter accounts and hashtags to follow.

The *communities of practice* framework focuses attention on a group of people as a site for learning, rather than the individual learner. The emphasis of communities of practice is on learning as a form of social participation (Wenger, 1998), an apprenticeship model where learning occurs as people become members of the group (Lave and Wenger, 1991). Communities of practice are marked by mutual engagement (i.e., reciprocity), joint enterprise, and a shared repertoire of artifacts or concepts that are collected or created by the group (Wenger, 1998). Past research has examined identity formation (Kimmons and Veletsianos, 2014) and sustained participation (Xing and Gao, 2018) in communities of practice hosted on social media platforms. Social media may be especially useful sites for potential participants to observe the norms of behavior and membership before engaging in more active and public ways (Bozkurt et al., 2020)—what Lave and Wenger (1991) termed legitimate peripheral participation en route to membership in the community of practice.

Finally, the *learning ecology* framework takes a system-wide view of learning to understand “the set of contexts found in physical or virtual spaces that provide opportunities for learning” (Barron, 2006, p. 195). An ecological perspective on networked professional learning is concerned with how all the pieces fit together to make a whole (Stevenson et al., 2019; Veletsianos et al., 2019). For instance, an educator may ask teaching-related questions in the r/Teachers subreddit (i.e., one of many distinct, theme-based discussion forums hosted on Reddit's platform) and learn about educational policy matters in the r/education subreddit (Carpenter and Staudt Willet, 2021; Staudt Willet and Carpenter, 2021) as a self-directed follow up to issues raised in a professional development workshop.

Affordances and constraints of social media as spaces for networked professional learning

Past research has shown that educators regularly use social media to connect with people beyond their local school, often around the world (Beach, 2017; Macià and García, 2016; Trust, 2012). Educators have voiced their appreciation for the ways social media frees them from temporal and geographical constraints, offering perspectives more diverse than would be available locally (Hur and Brush, 2009; Prestridge, 2017; Trust et al., 2016). Networked professional learning is particularly helpful for educators struggling with professional isolation (Carpenter and Krutka, 2014; Trust and Horrocks, 2017), such as those working in a small elementary school with only one teacher per grade level (Hur and Brush, 2009) or teaching a specialized content area like computer science (Yadav et al., 2016). In addition, Rehm and Notten (2016) found that educators continued to form new social connections as they spent more time on the social media platform Twitter. Other examples of social media affordances include new teachers developing a mentor network through Twitter (Smith Risser, 2013) and educators finding allies for justice-oriented teaching through social media movements like #EduColor (Bartell et al., 2019).

However, with these affordances come constraints that must be considered. For instance, although social media can connect educators to more voices offering purported expertise, these many voices present new challenges of reconciling conflicting messages about what and how to teach (Thompson et al., 2013). The ease of creating and disseminating content through social media also means that opportunities for networked professional learning can be lost in large amounts of spam (i.e., undesired or unrelated) messages (Carpenter et al., 2020). In addition, because of the sheer volume of resources available through social media, educators may have difficulty finding content that is useful and relevant. Problematic resources are also disseminated online alongside legitimate ones (Sawyer et al., 2019), and the global scope of resources raises a local-global tension where content needs to be adapted for a specific educational context (Jones and Preece, 2006). Finally, there are social constraints related to networked professional learning. For instance, past studies have reported a prevalence of self-serving behaviors among educators on social media (e.g., Prestridge, 2019; Staudt Willet, 2019), and Lantz-Andersson et al. (2018) speculated whether social media participation fosters collaboration or competition. Additionally, increased connectivity also increases expectations that educators should always be available and accessible to students (Fox and Bird, 2017; Selwyn et al., 2017).

Emerging issues in networked professional learning

Following the affordances and constraints of using social media for networked professional learning, there are numerous issues still in need of investigation. We conclude this section naming three issues, organized by the group of stakeholders, including teachers, administrators, and researchers. First, teachers need to continue to learn about the potential technoethical issues raised by seeking professional learning on social media. Krutka et al. (2019a) suggested six questions to answer when considering the use of a technology for teaching and learning:

1. Was this technology designed ethically and is it used ethically?
2. Are laws that apply to our use of this technology just?
3. Does this technology afford or constrain democracy and justice for all people and groups?

4. Are the ways the developers profit from this technology ethical?
5. What are the unintended and unobvious problems to which this technology might contribute?
6. In what ways does this technology afford and constrain learning opportunities about technologies?

Teachers and teacher educators should work to answer these questions with social media in mind when considering engaging in or recommended networked professional learning. Second, administrators and education leaders should be mindful of the identity-agency—that is, taking responsibility for and actively investing in one’s own self-development as a professional (Ruohotie-Lyhty and Moate, 2016)—required to initiate and sustain networked professional learning, which often occurs outside of traditional work hours. Past research has characterized this in a positive light, as a type of informal learning. Future studies should take a more critical approach (Selwyn, 2017; Watters, 2014) to explore networked professional learning as a new form of invisible labor. Through all these considerations, it is evident that networked professional learning spanning social media offers numerous new possibilities but also raises significant new perils.

Social media and learning: challenges and opportunities for the future of education

Looking across the sections above, we conclude with two challenges and opportunities for educational researchers and practitioners interested in the future of social media and learning in educational contexts. First, we have yet to fully understand the *role of social media in the classroom*, especially the multidimensional ways in which social media can be used effectively in classroom learning and associated challenges that must be navigated (e.g., ethical issues such as students and parents’ privacy concerns, forms of bias and discrimination propagated on social media). Whether considering how social media composition fits into literacy instruction or implementing social media activities as opportunities for relevant civic learning and engagement, further research is needed. Social media are recognized as important spaces where students spend significant time exploring, growing, and connecting with their communities outside of school, but the practices and pedagogies necessary to embed social media (or education about social media) into formal classroom settings are still being developed.

Second, we have yet to fully understand the relationship between *teachers’ use of social media for their own professional learning and its impact on their pedagogy*. Teachers’ perspectives on students’ social media use (e.g., valuing student writing on social media, recognizing social media as important platforms for civic engagement) directly impacts the role these media can play classroom learning. Teachers’ own use of social media, particularly for networked professional learning, also influence how their instruction *with* or *about* social media is taken up in school. Therefore, attention to educators’ social media use and how they integrate social media as part of their classroom content is critical to supporting effective social media learning practices. Teachers have the opportunity to acknowledge both technoethical issues and the importance of critical media literacy within their own networked professional learning and pass these skills and perspectives on to their students. Relatedly, just as students are spending significant time on social media, research shows teachers are also spending significant time learning and pursuing professional development on social media. Further research to understand this phenomenon and establish the value of teachers’ time spent on networked professional learning (e.g., recognition of effort or labor required, evaluation of content quality) is needed. Just as social media cannot be ignored as spaces integral to students’ literacy development and civic engagement—despite being commonly accessed outside of the classroom—so too must social media be acknowledged and explored as integral to educators’ teaching and learning.

Introduction

Throughout this section of the “International Encyclopedia of Education” covering “Learning, Cognition and Development,” contributors have offered insights into learning within specific fields of study, such as cognitive and neurological processes that underlie human learning and performance, developmental characteristics of children, adolescents, and adults, and trends in cognitive, biophysical, social-emotional, and moral development. Our goal in this article is to offer a global and integrated perspective that weds learning, cognition, and development under the banner of “learning across the lifespan.”

Moreover, we posit that marked changes in any of these critical areas will invariably affect other areas of study. As we will endeavor to document, much of learning that transpires in the domains and disciplines, which form the backbone of educational systems, is inextricably intertwined with cognition and development (Alexander, 2017). As the primary source of evidence for this integrated and lifelong view of learning, we will focus on the past decades of theory and research on the Model of Domain Learning (MDL)—a multidimensional model of development in academic domains and disciplines based on systematic changes in learners’ knowledge, strategic processing, and interest (Alexander, 1997, 2003). Before delving into the MDL, we briefly discuss relevant issues pertaining to learning across the lifespan, namely:

- Cross-theoretical principles of learning;
- The relation of learning and development; and
- Models of lifelong learning.

Cross-theoretical principles of learning

Numerous theories of learning exist within the extant literature—many of which are described in this volume—including behaviorism, social-cognition, cognitive constructivism, embodied cognition, and socioculturalism. Given such a wealth of theories that all seek to explain the nature of learning, it is easy to assume that there is no common ground shared by these diverse perspectives. However, Alexander et al. (2009), whose own theoretical orientations toward learning were appreciably different, set about the task of determining whether such common ground could be identified. What emerged from their in-depth exploration were general principles about the nature of learning that are shared by many disparate theories:

- Learning is change
- Learning is inevitable, essential, and ubiquitous
- Learning can be resisted
- Learning may be disadvantageous
- Learning can be tacit and incidental as well as conscious and intentional
- Learning is framed by our humanness
- Learning refers to both a process and a product
- Learning is different at different points in time
- Learning is interactional (p. 178).

Whichever theory one espouses, there is the underlying assumption that “learning brings about change.” Whether learning is neurophysiological, social, emotional, or cultural in nature; whether it comes about because of formal instruction or just from living in the world; or whether the learning occurs in specific content domains or is more generic, it will result in change. Whether that change may be imperceptible or dramatic, learning leaves its mark, nonetheless (Mahoney et al., 2018; Whitlock et al., 2006). What diverse theories also share is the view that “learning is inevitable, essential, and ubiquitous.” This means that learning happens to us all in some form and that human existence is predicated on the changes learning brings (Bargh and Chartrand, 1999). Moreover, the opportunities for and the sources of learning exist everywhere—in the world or in the mind.

Largely unvoiced but still underlying diverse theories is the acknowledgment that humans have the capacity to “resist learning” particular ideas or experiences (Alcorn, 2013; Finelli and Borrego, 2020). Perhaps the focus of that resisted learning conflicts with individuals’ prior understandings or strongly held beliefs or it is simply too distant from what they have experienced in their lives (Murphy and Mason, 2006; Sinatra and Hofer, 2021). Whatever the reasons, individuals may close their minds or divert their attention from such ideas or experiences. Yet, learners’ resistance may not be wholly successful in that some trace of the encounter may find its way into individuals’ or groups’ thoughts or awareness. It is also the case that learning cannot be presumed to be positive in all cases. There is simply too much evidence that individuals are exposed to incorrect or misleading information frequently or they misunderstand or misperceive what they see or hear (Lombardi et al., 2016). Inaccurate or misleading information can also unknowingly distort what is learned subsequently (Vosniadou and Mason, 2012). In that way, “learning can be disadvantageous.” Further, although it is recognized that schools are institutions that are formed, in part, to facilitate learning for children, youth, and adults within a community or society, learning cannot be confined solely to classrooms or to formal education (Dabbagh and Kitsantas, 2012; Rogoff et al., 2016). As we discussed, learning can occur at any place humans move in the world. Even more to the point, learning can transpire without individuals’ awareness that it is happening and without any explicit goal on their part. Thus, learning can be both “tacit and incidental” as well as “conscious and intentional” (Javis, 2009).

Another shared premise about learning, not expressly considered but tacitly accepted by most, in many theories of learning—with the exception of embodied cognition (Lakoff and Johnson, 1980)—is that “learning is framed by our humanness.” It is easy to overlook the fact that, as humans, we enter the world with certain neurobiological capabilities and constraints that distinguish us from other living creatures and shape how and what we learn. For example, our ability to see, hear, smell, touch, our sensory faculties, afford us access to the empirical world and become the raw materials of our learning (Martin and Martin, 2011). Similarly, the configuration and maturation of our brains and the inner workings of our minds give us the means to perceive, think, reason, feel, and imagine (Baruch et al., 2019). It is also evident that variations in these human capabilities and their affordances can influence the “how” and “what” of learning. Even relatively minor problems with sensory systems, for example, can translate into differences in information access, perceptions, or interpretations.

Theories of learning are essentially explanatory frameworks meant to capture how learning unfolds—that is, the process of learning. These theories may well differ in whether they are expressly interested in what this process looks like within the mind of one person or within an entire sociocultural group or community. For instance, theories represented in this volume may set out to explain how rewards and punishments bring about change, or how individuals’ participation within social or cultural communities shapes their understanding and view of the world. Yet, the process per se is but a facet of what learning signifies. Learning also refers to the outcomes that arise from the process. For cognitivists, those products of learning may take the form of knowledge stored and organized in the mind, whereas to socioculturalists the products of importance are found in the demonstration of practices valued within the community. In this way, “learning is both a process and a product.”

As may be evident through this discussion, learning can occur at any time and any place and can be markedly affected by conditions that exist at that moment in time. However, it is important to keep in mind that learning, as a process, also unfolds over time and over many contexts. Consequently, “learning is different at different points in time.” As individuals or groups develop with the passage of time, or as the conditions and contexts of learning shift, the processes and products of learning will correspondingly manifest change (Vygotsky, 1978). Contributors to this volume have offered rich descriptions of the physical, neurocognitive, social, and emotional characteristics of those in infancy, childhood, adolescence, and early and late adulthood. The developmental differences across these age ranges have direct implications for the nature of learning and the types of learning that are regarded as “typical” (Bjorklund and Pellegrini, 2002). Similarly, important distinctions in the contexts and the content of learning are associated with these age ranges. We will delve deeper into the alignments between development and learning later in this article.

According to Alexander et al. (2009), “learning is interactional,” in that “learning engages an intermutual sequence of operations that are shaped by human culture and biology ... and by how humans act and react to a dynamically changing world” (p. 180). Such interactivity pertains not only to the person and their environment, and the person and their culture or biology, but also pertains to the interpersonal. Whether through an exchange of ideas by means of discussion and dialog (Murphy et al., 2009) or by observing and modeling the actions of others (Bandura, 1989), persons who populate the environments in which individuals live and learn are as critical to learning interactionally as the cultural artifacts and educational resources that are present in the environment (Bandura, 1989).

With this overview of the cross-theoretical principles of learning complete, we want to put forward the claim that learning, and especially learning across the lifespan, is a form of development. In the following section, we will attempt to make a compelling case to that effect.

Learning and development

In 1978, Vygotsky addressed the provocative question of the relation between learning and development. His intention was to cast doubt on the researchers and theorists who espoused what he regarded as extreme positions on this foundational but unsettled issue. At one extreme were experimental studies in development, like those conducted by Piaget, that were designed under the assumption that thinking, reasoning, and causal determinations unfolded in the mind of the individual in the absence of any external influences such as schooling or the support of others. At the other extreme was the work of psychologists like Binet, who assumed “that development is always a prerequisite for learning” (p. 35). Thus, if individuals’ minds had not matured sufficiently, instruction dealing with content or mental processes would be futile.

Vygotsky’s alternative to those extreme perspectives on learning and development was his conceptualization of the Zone of Proximal Development (ZPD). Through the ZPD, Vygotsky laid the groundwork for his claim that there were two developmental levels that had to be taken into consideration if researchers and theorists wanted to grasp the true relation between learning and development. The first level, which he labeled the “actual developmental level” (Vygotsky, 1978, p. 37), refers to those mental abilities or cognitive processes individuals demonstrate on measures or tasks that are decontextualized and that occur in the absence of feedback or support. The second level, identified as the “potential developmental level,” pertains to the mental abilities or cognitive processes individuals manifest when supports or guidance are made available. ZPD signifies the difference between these two developmental levels—actual and potential.

Consistent with Vygotsky’s contention, many contemporary theorists and researchers recognize the difference between what children, adolescents, or adults can “typically” and “independently” demonstrate on assessments or tasks, and what they may demonstrate under more favorable conditions (White and Alexander, 1986; Gelman, 1979; Goswami and Bryant, 2007). For instance, stage theories of development regard the cognitive functions required of analogical reasoning to be beyond the capabilities of young children (Case, 1972; Piaget, 1952). However, White and Alexander (1986) set out to determine whether 4-year-old children would manifest analogical reasoning when presented with analogy problems of the form A:B::C:D. These analogy problems were composed of attribute blocks common in their preschool environments and cast as a game. Similar to what Gelman (1979) and others (Goswami and Bryant, 2007; Veenman and Spaans, 2005) had reported, White and Alexander (1986) found that these young children were indeed capable of reasoning analogically when materials were familiar, the context was comfortable and supportive, and the task was engaging.

Therefore, when developmental profiles of young children, adolescents, or adults are forwarded, as they are in this volume, it is important to keep in mind that researchers are likely portraying typical capabilities, characteristics, and tendencies. These authors are not, by default, discounting the possibility that individuals might demonstrate higher levels of performance on certain tasks presented under particularly favorable conditions or with the guidance of a more knowledgeable other, as was exhibited in Vygotsky’s (1978) ZPD experiments. Further, this discussion is a reminder that learning and development are not wholly separate phenomena in humans of any age or background. Moreover, rich environments and appropriate instructional practices can promote “both” learning and development (Darling-Hammond et al., 2020). In this way, learning impacts development, just as development impacts learning. Further, this reciprocity is not only limited to cognitive capabilities but extends to many areas of human functioning, including social, emotional, and moral development.

While much of the theoretical and empirical research that addresses the interplay between learning and development has focused on very young children or students in primary through secondary school, their joint influence is evident well beyond the classroom context and well into the later stages of life. In the ensuing section, we will overview models of lifelong learning that make this continuing influence apparent.

Learning across the lifespan

For educational researchers, questions about learning are most often directed toward school-aged children and adolescents; that is, preschool through higher education. Of course, learning begins well before young children enter nursery or preschool and continues long after compulsory education is over. In effect, learning is on-going from “cradle to grave.” Similarly, the span of human development has been graphically described as “womb to tomb.” Humans are always in the process of change in terms of their learning and their development. Also, understanding the changes that unfold across the entire lifespan is crucial for those who seek to promote learning within individuals or for the enhancement of societies. Therefore, we will survey the literatures in two areas that consider such expansive changes over time; learning across the lifespan and lifelong learning.

Conceptualizations

“Learning across the lifespan” and “lifelong learning” are ideas to which many laypersons can relate; that is to say, many individuals are comfortable with what these terms generally mean. Yet, whether those laypersons could offer a very clear or precise definition of either term or discuss possible differences between them is quite another story. Even more intriguing for the purpose of this article is that there is a similar lack of conceptual clarity or specificity surrounding each of these popular concepts in the expanding scholarly literature (MacLachlan and Osborne, 2009; Schuetze and Casey, 2006). Fleming (2011) echoed this very concern in the introduction to the “Oxford handbook of lifelong learning.” Specifically, he observed that: “As lifelong learning does not have great conceptual

clarity this may explain how it has become a highly accepted concept; like apple pie, it is difficult to be against it!" (p. 32). The same could be said for learning across the lifespan (Istance, 2003; Tuijnman and van der Kamp, 1992). While there do appear to be relevant differences between these two bodies of literature that require our consideration, such as their disciplinary roots and their overarching aims, we will first identify areas of convergence. That is, what characteristics do these two critical domains of inquiry have in common?

Commonalities

The themes and foci that learning across the lifespan and lifelong learning seemingly hold in common are the following:

- Learning cannot be constrained to specific years of life or to particular environments.

As we noted at the outset of this section, learning occurs at each stage of life and happens in every space that humans occupy. It is not only cradle to grave but also in-school, out-of-school, and in the workplace (Javis, 2009; OECD, 2021). On that point, theorists and researchers in the domains of learning across the lifespan and lifelong learning concur.

- The well-being of individuals and societies encompasses many to all facets of human existence including cognitive, social, motivational, socioeconomic and biophysiological.

A theme of this article has been the multidimensionality of human learning and development. That theme applies to theory and research related to learning across the lifespan and lifelong learning. Thus, attention in these literatures is paid not only to cognitive abilities or academic learning, but also to physical and mental health, and to socioeconomic wellness (Elfert, 2015; Sheffler et al., 2021).

- The developmental changes that occur for individuals, especially those who are among the most senior members of society, are significantly tied to their well-being, independent functioning, and their contributions to their social groups, communities, and society.

Change is inevitable for all humans who populate this planet. Still, the nature of the changes associated with aging may be especially relevant to those concerned with learning across the lifespan and lifelong learning (National Academies of Science, Engineering, and Medicine [NAS] 2018; OECD, 2021). There are certain decrements commonly associated with advanced age, such as declines in physical strength and mobility, memory, or mental agility (Sheffler et al., 2021; Tuijnman and van der Kamp, 1992). Yet, those invested in learning across the lifespan and lifelong learning appreciate that there are actions and programs that ameliorate such declines (e.g., reduce cognitive decline associated with dementia) and enrich the lives of all members of society, regardless of age (Fleming, 2011; London, 2021).

- Learning across the lifespan and lifelong learning are influenced by conditions and forces that are internal and external to the individual.

Whether individuals struggle or thrive over their lifetime is dependent on a confluence of factors. Some of those factors are specific to the person, such as their mental acuity, personal interests, or acquired knowledge (Javis, 2009; Volles, 2016). Equally important, however, are conditions external to individuals which might include healthy living conditions, educational opportunities, and professional development resources (Schuetze and Casey, 2006). How these internal and external factors shift over time becomes consequential for the continued learning and development under both frameworks.

- There are actions that can be taken or policies that can be instituted to promote learning across the lifespan and lifelong learning.

Another commonality in these two literatures is their shared focus on enhancing learning in a manner that improves the lives of individuals or contributes to the betterment of society (Darling-Hammond et al., 2020; Fleming, 2011). These ends may be pursued through specific programs that offer training or support in areas of need such as professional development, counseling, or medical assistance (Brown et al., 2015). Alternatively, the avenue for improvement may take the form of competencies or standards articulated for fields of study or professional domains, or state or national policies that are meant to ensure that adequate attention or fiscal resources are made available (Takayama, 2013).

Distinctions

Beyond the aforementioned goals, emphases, or actions shared by those identified with learning across the lifespan and lifelong learning, there are important ways in which these lines of inquiry diverge. For one, works that speak to learning across the lifespan more often represent an educational, psychological, or developmental perspective. Thus, the emphasis in these writings is typically on how to promote the overall cognitive, social, emotional well-being of individuals; facilitate their ability to develop to their fullest potential; and to acquire new knowledge and skills regardless of age, background, or physical limitations.

Because of the educational orientation represented in this literature, there is also more attention paid to systematic changes in specific domains of learning or arenas of professional practice. Such a framing was evident in "How People Learn II: Learners, Contexts, and Cultures," a volume published by NAS (2018). The contributors intended this book to serve as a tool that could

“enrich discussions about research and practice in education and learning for people of all ages” (p. ix). In keeping with that goal, the contributors dedicated an entire chapter to this subject.

Although there was no definitive definition proffered, contributors to this article noted that learning across the lifespan operates principally outside of compulsory education and is motivated largely by individuals’ personal choices and life circumstances and by shifts in their cognitive, physical, and socioeconomic resources and capabilities. The rich discussion of learning across the lifespan in this article was synthesized into two major conclusions:

CONCLUSION 9-1: People continue to learn and grow throughout the life span, and their choices, motivation, and capacity for self-regulation, as well as their circumstances, influence how much and how well they learn and transfer their learning to new situations.

CONCLUSION 9-2: People learn continually through active engagement across many settings in their environments; learning that occurs outside of compulsory educational environments is a function of the learner’s motivation, interests, and opportunities. Engagement with work (especially complex work that involves both intellectual and social demands), social engagement, physical exercise, and adequate sleep are all associated with lifelong learning and healthy aging (p. 223).

In comparison to this more educational and developmental perspective, the literature on lifelong learning has a more competency-based, sociopolitical, or economic focus, as well as a greater input from those working in adult education. Key international organizations, such as the United Nations Educational, Scientific and Cultural Organization (UNESCO) and the Organization for Economic Co-operation and Development (OECD), have become the driving forces for the rising attention to lifelong learning for many countries. The rationale for this growing interest globally can be seen in the introduction to “OECD Skills Outlook 2021: Learning for Life:”

Individuals’ ability to adapt and thrive in a fast-evolving world rests on them having acquired strong foundation skills, the willingness to learn and a habit of learning (otherwise known as lifelong learning attitudes). These skills and attitudes are vital for them to absorb and expand the knowledge and skills required to navigate new labour-market needs and life circumstances. However, walking the talk of lifelong learning requires a change in mindset: from a vision of learning that is compartmentalised in different phases of life to a process that evolves during all of life (Foreword, p. 1).

The economic implications of lifelong learning and the availability of a competent workforce are central themes of this report and others issued from world organizations.

According to Volles (2016) and Bynner (2017), critical analysis of policy documents from UNESCO and OECD reveals a progression away from a more humanistic orientation to a perception that lifelong can be used “as a cure for a wide range of maladies, ranging from high unemployment to low innovation rates and a lack of entrepreneurship” (Volles, 2016, p. 343). Further, the emphasis on essential competencies and skills required for success in a knowledge-rich and technology-based economy has resulted in efforts to specify what the educational agenda should be, especially for adult populations. Technology-specific competencies and skills, not surprisingly, figure heavily among those essentials for future success.

The importance of adult education or re-education was clearly apparent in the contributions to the first Oxford handbook of lifelong learning (London, 2011). For instance, the programs, technologies, and techniques detailed in this volume were expressly targeted to the workplace, and notably to employees or executives in the corporate and business world. Those thrusts are still evident in the second edition of the handbook (London, 2021) but with more attention being given to continuing education, professional development, and to career survival shaped by technological advancements.

The Model of Domain Learning

In this closing section of the article, we want to overview the Model of Domain Learning (MDL; Alexander, 1997, 2003). We have chosen to devote space to the MDL for two reasons. First, it illustrates how one theoretical model portrays the interplay of learning and development, capturing this interplay by explicating how learning and learners systematically change over time as a result of maturation and experience (Alexander et al., 2009). Second, as discussed in the preceding section, the MDL serves as an example of learning across the lifespan. There are several reasons why the MDL fits best within the literature on learning across the lifespan rather than lifelong learning.

The MDL and learning across the lifespan

Several features of the MDL place it more squarely within learning across the lifespan. For one, the MDL describes change at the level of the person and not society (NAS, 2018). For another, the realm under consideration is educational instead of economic or sociopolitical. Moreover, the goal of the MDL is the optimization of human potential and not the redress of global issues such as migration, underemployment, or economic sustainability (Darling-Hammond et al., 2020). Also, the theoretical and empirical literature grounding the MDL comes from psychology, development, academic domains, and fields of professional practice with limited attention to adult education, professional development, or geo-economics (Alexander, in press). Finally, there is recognition of the importance placed on learners’ motivations and on their investment in self-regulation and goal

Fig. 1 The components and stages of the Model of Domain Learning.

attainment (Dabbagh and Kitsantas, 2012; Sheffler et al., 2021). At its core, the MDL seeks to answer the question of how individuals change in their knowledge, strategic processing, and their interests as they become more and more competent in a given field of study, such as mathematics, history, or computer science. In this way, the goal of mapping those changes reflects learning across the lifespan (Alexander, 2003).

Specifically, the MDL is a theoretical model of expertise development comprising three stages: acclimation, competence, and proficiency/expertise. The characterization of each stage comes from the shifting relations among individuals' breadth (domain) and depth (topic) of subject-matter knowledge, their reliance on surface-level or deep-processing strategies, and their enduring (individual) or fleeting (situational) interests (see Fig. 1). Although it is a model of expertise development, the MDL is not intended only for those seeking to become experts, particularly since only a very small percentage of individuals actually achieve expertise in any domain (Alexander, 1997). Rather, from the onset of "acclimation"—the moment of earliest exposure to a domain such as reading or science—individuals unknowingly embark on a journey that should carry them toward greater competence or capability in that domain. How long and how far students progress in this journey and, concomitantly, how competent they ultimately become, is highly dependent on both internal forces (e.g., underlying capabilities, goals, and efforts) and external factors (e.g., opportunities and resources) that arise during this developmental journey. Among the influential factors that can foster or frustrate progress in any academic domain is the quality and support students receive while engaged in formal schooling (Darling-Hammond et al., 2020). A quality education that is also well matched to learners' personal goals, sociocultural background, and specific strengths and needs can do much to propel them forward in their academic development.

The MDL and traditional models of expertise

Unlike more traditional models of expertise (Ericsson and Charness, 1994), the MDL does not simply categorize the populace as either a novice or an expert nor assume that hours of deliberate practice alone will lead to expertise. Instead, the model represents the movement toward expertise as beginning in acclimation, the stage where individuals initially become oriented to the domain in question. Once they have acquired a foundation of domain-specific knowledge, problem-solving strategies, and manifest personal interest in that field of study, learners cross over into the stage of "competence." Competent individuals operate with a growing and more integrated body of subject-matter knowledge, use both surface-level and deep-processing strategies when encountering domain problems, and form personal connections to the domain that are less reliant on features of the environment that may prove stimulating or intriguing but potentially volatile and fleeting. Competence, in the MDL, is the stage of development that most students reach for fields that form the backbone of school curricula in primary, secondary, and tertiary education.

Because of its expansive and diverse nature, competence is subdivided into early, middle, and late periods. As seen in Fig. 1, noticeable differences in individuals' knowledge, strategic processing, and interest are evident in these subdivisions. Of particular importance to learning across the lifespan is mid-competence. According to Alexander (2003, in press), it is at mid-competence that those who identify strongly with a domain and are committed to the pursuit of expertise seek out experiences that can contribute to

their continued development. These experiences will typically extend well beyond the years of compulsory and tertiary education. Those who elect to continue their journey toward expertise may succeed in reaching the proficiency or expertise stage of the MDL. As captured in Fig. 1, individuals at this stage are predicted to manifest an abiding interest in and self-identify within the domain. Further, because experts are expected to contribute new knowledge to their domain, they would necessarily rely on the deep-processing strategies required to re-envision and transform that field.

From the standpoint of learning across the lifespan, we want to emphasize that achieving expertise is not the culmination of learning and development according to the MDL. Domains of learning are never stagnant. They continue to expand or shift over time. Thus, to maintain their expertise, those in proficiency must continue to learn, grow in their understandings, and perhaps even shift their views or perspectives. Moreover, as we have suggested, the journey toward expertise can consume decades of one's life. During those ensuing years, those pursuing expertise have undergone all manners of change—cognitive, biophysical, social-emotional, or socioeconomic. Those developmental changes will naturally influence individuals' capacity and desire to meet the challenges that inevitably will arise on this lifelong journey.

Concluding thoughts

Our overarching goal in this chapter was to demonstrate how learning and development are intertwined across individuals' lifetime. By surveying the principles of learning from Alexander et al. (2009), for example, we wanted to illustrate that even theories of learning that differ in significant ways still largely adhere to these principles. We then looked more specifically at contrasting views of the relation between development and learning, turning to Vygotsky's (1978) Zone of Proximal Development as a bridge between these contrasting perspectives on learning and development. With these foundational elements in place, we wanted to examine two viewpoints on how learning may unfold from cradle to grave—learning across the lifespan and lifelong learning. Through this discussion, we sought to illustrate how these two approaches converge on certain premises and practices while diverging in other important ways. The final topic in this article was the Model of Domain Learning (Alexander, 1997, 2003). In this overview of the MDL, we sought to highlight one model that brings together learning and development by describing individuals' journeys from acclimation through competence and, potentially, to proficiency or expertise. This journey, which falls under the banner of learning across the lifespan, brings together cognitive, strategic, and motivational dimensions of learning and development. By understanding the complexity of learning across the stages of human development, individuals and those guiding their journey at each developmental stage can be better prepared to navigate the challenges that will undoubtedly be encountered and to relish the experience of a lifetime.

Introduction

Infancy is a period marked by rapid learning about infants' physical and social worlds. With time, and experience, infants meet this formidable challenge by becoming robust, efficient, and active learners. Decades of research examining learning through infancy point to several learning mechanisms, including those that promote learned associations, statistical learning, and social learning. To date, most of the prior studies on infants' learning have investigated how different learning mechanisms facilitate learning achievements in isolation and under a high degree of experimental control. These studies have provided a wealth of information and confidence about the existence and the strength of the learning tools available to infants. Despite these important and extensive insights, many of infants' learning achievements have not been explained and comprehensive models of infants' learning across diverse domains remain elusive. Having set the foundation for the development of comprehensive frameworks, we argue that the critical next step is to consider the combined influence of multiple mechanisms and how they function together to support the rapid knowledge and skill development evident in infancy. In this contribution, we bridge the gap between seminal and recent research on three key individual mechanisms by describing approaches that have sought to integrate two or more types of learning and reflect on how integrative approaches will be key to achieving a comprehensive understanding of the mechanisms and processes that support infants' learning and development.

Learning in infancy

Associative learning

General learning mechanisms (GLMs) provide infants with the ability to learn by association from the moment that they are born. Learning by *association* occurs when learners make connections between pieces of information that are perceptually salient, co-occur either at the same time, or within a constrained temporal window. Infants' early abilities to rapidly associate the words that they hear with the appropriate aspect of the world around them (i.e., the referent) is often lauded as showing the power of learning by association (Plunkett, 1997; Smith, 2000). Within associative accounts of word learning, infants assign a novel word, such as a new object label, onto the object or aspect of their environment that is the most salient to them when they hear the word (Hollich et al., 2000; Smith et al., 2003; Werker et al., 1998). Associative learning has been argued to get infants' word learning off the ground and thus, has been linked with infants' word learning throughout the first year and a half of their lives (Byers-Heinlein et al., 2013; Colunga and Smith, 2005; Hollich et al., 2000; Smith, 2000).

Beyond word learning, associative learning within and across modalities is imperative across diverse domains such as the development of concepts (Sloutsky and Deng, 2019), object categories (Goldstone and Barsalou, 1998; Johnson et al., 2003; Rakison et al., 2008), body representations (de Klerk et al., 2021) and, even, fear (Rakison, 2022). To illustrate the role of associative mechanisms in infants' categorical learning, we draw on work examining an early emerging category distinction that infants as young as

9 months make—the distinction between animate (i.e., people, insects, animals) and inanimate (e.g., plants, vehicles, tools) things in their world (Poulin-Dubois et al., 1996). There is little doubt that perceptual aspects of objects, such as shape, color, and patterns of movement, are employed to make such category decisions (Goldstone and Barsalou, 1998; Quinn and Eimas, 2000). Yet, infants also distinguish between members of divergent categories that are perceptually similar (e.g., plane versus outstretched bird). One explanation is that infants become familiar with the co-occurring physical attributes of objects through associative learning. In the case of the plane versus outstretched bird example raised above, infants learn relevant part-level perceptual details of objects, such as vehicles often have wheels whereas animals often have legs, as they begin to appreciate the distinctions between object categories, such as animate versus inanimate objects.

While evidence clearly suggests that associative mechanisms catalyze infants' early learning, associative learning cannot account for all of the learning that infants demonstrate for two key reasons: (1) learning by association can be time intensive and (2) the world of an infant is often filled with ambiguity in which there is a vast array of incoming signals that may often be equally salient and thus, relying on associative learning as the sole learning mechanism would often produce learning errors. Within the word learning domain, the limitations of associative learning accounts are best illustrated by Quine's problem of reference (Quine, 2013; Quine and Van, 1960): for any novel word one encounters, there is often an infinite number of potential referents for the word, many of which do not always "stand out" of the realm of possibilities (see also Blythe et al., 2016; Hollich et al., 2000). Indeed, learning solely through associations would be a slow process filled with errors, which does not adequately capture infants' learning.

Statistical learning

Fortunately, infants' learning is boosted by an early-developing, remarkable ability to detect patterns across a diverse range of stimuli and contexts (for reviews see Erickson and Thiessen, 2015; Krogh et al., 2013; Romberg and Saffran, 2010; Saffran, 2020; Saffran and Kirkham, 2018; Thiessen et al., 2013). Studies focusing on infants' language learning have been critical for our understanding of how infants harness the statistical regularities in their environments for learning; *statistical learning* (Ellis et al., 2021; Saffran, 2020). The results of this work demonstrate that infants are sensitive to the statistical regularities within the languages to which they are exposed (Johnson et al., 2003), which are informative based on their predictability and redundancy (Romberg and Saffran, 2010; Tenenbaum et al., 2011). In their pioneer study, Saffran et al. (1996) demonstrated that infants as young as 8 months of age detect the statistical regularities (i.e., transitional probability of sounds) present within and between word boundaries using a familiarization-preference language perception task (Jusczyk and Aslin, 1995). During an initial familiarization period (~2 min), infants were presented with an uninterrupted stream of an artificial language comprised of four nonsense words each with three syllables (e.g., bidakupadotigolabubidaku ...). Infants' attention toward test trials where the speech was either consistent or inconsistent with the statistical properties of the familiarization stimulus was recorded. Infants looked reliably longer during the inconsistent test trials providing evidence that they could detect the statistical regularities present in a language, even when that language is new to them. Since this study, numerous investigations have documented the role that infants' sensitivity to statistical regularities plays in their language development (for reviews see Erickson and Thiessen, 2015; Krogh et al., 2013; Romberg and Saffran, 2010; Saffran, 2020; Saffran and Kirkham, 2018; Thiessen et al., 2013). Beyond language learning, there is a broad recognition of the potential power of statistical learning to underpin infant learning across various domains and modalities (Smith et al., 2018), including laying the foundation for infants' learning about objects (Colunga and Smith, 2005; Fiser and Aslin, 2002; Johnson et al., 2003), object sequences (Kirkham et al., 2002), and even infants' socio-cognitive understanding (Ruffman et al., 2012).

Statistical learning studies have revealed at least three types of statistical learning that infants demonstrate including: conditional, distributional, and cue-based statistics (Thiessen et al., 2013). *Conditional* statistics are regularities defined by how often two (or more) events, objects, or object features co-occur conditionally upon one another. Infants are sensitive to events that co-occur frequently (A and B), and as noted above, events or objects that are presented together frequently are typically learned together via association. However, in conditional statistical learning, the association between A and B is strongest when A and B occur together more often than when they occur individually. Infants become attuned to the co-occurrences of these pairings over time as indicated by their learning to expect B when A is presented. The study by Saffran et al. (1996) described above provides evidence that infants are sensitive to the transitional probabilities of recently learned sound pairings within and across word boundaries.

Infants notice conditional regularities in stimuli other than speech stimuli, including stimuli that is nonadjacent (i.e., learning that A always precedes C if exposed to sequences like ABC, ADC, BAC etc.) (e.g., Creel et al., 2004) and infants' own and others' action sequences (e.g., Baldwin et al., 2001). To illustrate, Fiser and Aslin (2002) demonstrated that infants 8 months of age who were repeatedly shown scenes with elements that occurred together according to different conditional probabilities found that infants preferred to look at scenes that contained the elements that were consistent with the conditional probabilities to which they had previously been exposed. Together, evidence illustrates that before their first birthdays, infants demonstrate a robust sensitivity to the conditional probabilities present in the input they receive across multiple modalities.

A second type of statistical learning reviewed by Thiessen et al. (2013) is *distributional* statistical learning, which is characterized by a sensitivity to differences in how often different sets of events or stimuli occur together relative to how often other sets of events or stimuli occur. For example, an infant's category of "bird" constructed through distributional statistics is likely to include

exemplars that all have properties such as has wings, a beak, and can fly. This category would help infants successfully categorize new birds they encounter into the category so long as the new bird has properties that are shared with the exemplar(s) (e.g., flamingo), but less likely to do so for an atypical bird (e.g., penguin or kiwi). Infants' ability to use distributional statistics to learn category boundaries has been demonstrated in the domains of objects (e.g., Rakison, 2004; Younger and Cohen, 1986) and language (e.g., Maye et al., 2002; Thiessen and Yee, 2010; Werker et al., 2007).

Given a very noisy environment, statistical learning of conditional and distributional regularities would require a great deal of exposure before consistent patterns are detected. This is because the learning context for infants is expansive and usually contains a diverse set of events and objects simultaneously (consistent with the critique of associative learning in **Associative learning** section). A third form of statistical learning, *cue-based* statistics, helps overcome this limitation. Cue-based statistics occur when an obvious perceptual property acts as a cue for a less obvious, conceptual property with which it is associated. An example of this is a speaker's use of pauses or different speech stress patterns, which are common cues that signal boundaries between words. In the non-linguistic domain, cue-based learning has been linked to an individuals' ability to use biological motion to distinguish between animate versus inanimate stimuli. Learners learn the cue through a sensitivity to the weighting of a particular cue with respect to how likely the cue is present with a particular property. Importantly, cue-based statistics are not restricted to a single instance or pairing but are applied (i.e., generalized) to other, unfamiliar, situations that involve the same cue, suggesting that once learned, the cue can fuel subsequent learning (for a review see Thiessen et al., 2013).

We have summarized three forms of statistical learning that have been demonstrated by infants across linguistic and non-linguistic domains of development. Infants' sensitivity to a range of statistical regularities in their environment clearly provides them with the tools they need to develop a broad base of knowledge, which has been supported by recent evidence linking 18-month-old infants' statistical learning skills in a language perception task with their subsequent vocabulary development (Ellis et al., 2021). While statistical learning clearly supports infants' learning in important ways, focusing on statistical learning mechanisms overlooks another form of learning that defines infancy—social learning.

Social learning

Decades of research has shown that infants exhibit a remarkable ability to learn through observations of and interactions with the individuals in their social world. This type of learning, aptly named *social learning* (e.g., Heyes, 1994), is argued to be particularly important for infants' learning of knowledge that is difficult, if not impossible, to uncover on their own, such as how to use novel objects (Barr et al., 1996; Meltzoff, 2010; Nielsen, 2006; Want and Harris, 2002) or cultural conventions (Csibra and Gergely, 2006; Henderson et al., 2008; Legare, 2017; Tomasello et al., 2010). To illustrate the power of social learning, consider how an infant might learn how to eat applesauce in a bowl that has been placed beside a shiny object that they have never used (i.e., a spoon). The infant could learn this skill through trial-and-error by experimenting with diverse ways to get the sauce into their mouth (e.g., try to use their hands, lift their bowl to their face, become distracted by making noise with the spoon), all of which are likely to be ineffective and messy! However, it is more likely that the infant would recruit their keen social learning skills and learn how to eat the applesauce by watching their people around them use their own spoons to successfully move the applesauce from their bowls to their mouths with minimal mess or loss of the delicious food. Social learning emerges early in infancy and encompasses learning that is enhanced or achieved via the presence or actions of a social partner across various domains (Heyes, 1994; Rendell et al., 2011).

Infants demonstrate their social learning in diverse ways, including by copying (i.e., imitating) others' actions (Barr et al., 1996; Elsner, 2007; Hayne et al., 2000) and using others' emotional expressions to guide their behavior (i.e., social referencing; Feinman, 1982; Stenberg, 2009; Walden and Ogan, 1988). We highlight infants' exceptional social learning skills by reviewing the development of imitation through infancy.

Imitation and emulation

Imitation studies have been used extensively to study generalized learning across infancy as imitation paradigms capitalize on infants' propensity to copy the gestures and/or outcomes produced by others while also having low language requirements, making such paradigms suitable for preverbal infants. In imitation tasks, a demonstrator shows the infant how to perform an action or sequence of actions on a novel object to complete a goal (e.g., puzzle as per Dickerson et al., 2013; Jones, 2009 for a review). This process is often repeated several times, particularly with younger infants who show memory benefits from multiple repetitions (Barr et al., 2007). Then the infant is invited to act on the object and their reproduction of target action(s) and goal(s) are recorded as an indicator of learning. Multiple types of social learning strategies around behavioral copying of the actions of others have been identified including mimicry, imitation, and emulation. *Mimicry* is defined as behavioral copying of another's actions without the knowledge of whether the copying was an intentional behavior elicited by the infant, or a reflexive response (Davis et al., 2021; Huang and Charman, 2005; Slaughter, 2021). Once infants develop an understanding of others' intentions, they engage in *imitation*, the copying of demonstrated actions and goals, and *emulation*, a term coined to describe the copying of the goals of the demonstrator without direct copying of the actions produced (Huang and Charman, 2005; Nielsen, 2006).

Early investigations of infants' imitation suggested that infants just days old could imitate others' facial expressions (Meltzoff and Moore, 1977). However, mixed evidence from subsequent work sparked debate about neonates' abilities to reliably imitate (Davis et al., 2021; Slaughter, 2021). More recent evidence suggests the earliest signs of imitation emerge between 4 and 7 months of age as indicated by infants' abilities to reliably mimic social partners' facial expressions and gestures (Hashiya et al., 2018; Iso-mura and Nakano, 2016).

Although early ontogeny is rife with learning statistical regularities, the prioritization of social information and the emergence of imitation as a robust learning tool emerges by 14 months (Meltzoff, 1985). In one study, Barr et al. (1996) investigating immediate and *deferred imitation*, where infants' imitation is tested after a delay (of hours to days), infants aged 14 months and 24 months showed evidence of learning a one-step action sequence and retaining that information after a 24 h delay. Age-related effects were evident, such that 24-month-olds performed better than 14-month-olds. Several studies have shown age-related increases in imitative learning, with the earliest accounts showing that infants as young as 6 months can imitate a one-step action immediately and after a 24 h delay when the action is demonstrated repeatedly during the learning phase (Barr et al., 1996). With increases in memory flexibility and information processing capabilities, older infants can tolerate greater delays between learning and test and can imitate more complex action sequences and goals (Barr and Hayne, 2015; Hayne et al., 2000).

How do researchers know when infants are engaging in "true" imitation where they understand the demonstrator's goal? Two examples of infants' social understanding underlying their imitation come from the findings of emulation studies. In these studies, infants are presented with a task for which there are multiple ways to achieve the task goal. For example, when completing a puzzle, the demonstrator may slide the puzzle pieces together using two fingers, but the goal (i.e., to complete the puzzle) can be achieved using any number of other actions (e.g., grasp puzzle pieces and slide, pick up and move puzzle pieces). When infants understand the goal and that actions are goal-directed, they may emulate, that is, they complete the task in a more efficient manner than that which was demonstrated (Huang and Charman, 2005; Matheson et al., 2013; Moser et al., 2015). Studies investigating the conditions under which infants use an emulation strategy reveal factors such as age and task complexity influence whether infants choose an imitation or emulation strategy (Huang and Charman, 2005; Nielsen, 2006).

Another social learning strategy that has been identified is *overimitation* where infants faithfully imitate a demonstrator's actions even when they are not related to attaining the goal, or when a more efficient strategy is available (Keupp et al., 2013, 2018; Lyons et al., 2007). Theories about the phenomenon of overimitation propose that infants may lack the understanding that the demonstrator's actions are not casually related to or relevant to the goal (Flynn, 2008; Lyons et al., 2007), recognize actions as goals in and of themselves when the demonstrator increases their salient (Keupp et al., 2018), or possess motivations to be affiliative (Over and Carpenter, 2012). The last two accounts suggest that, around their second birthday, infants emphasize the social aspects of social learning at the expense of more efficient learning, demonstrating the power of social learning.

The imitation work described above reveals that information conveyed socially becomes an important means of learning new skills in infancy, particularly after the first year following improvements in memory, information processing, and physical abilities (e.g., dexterity during object manipulation).

Foundations of social learning

Infants' social learning is supported by several early emerging behavioral patterns, such as a sensitivity and responsivity to social and communicative cues, social contingency, and behavioral mimicking, all of which lay the foundation for social learning mechanisms to develop. Sensitivity to social stimuli, such as faces (Guellai and Streri, 2011), gaze direction (Batki et al., 2000) and biological motion (Simion et al., 2011) emerges within the first year. Newborns, for instance, not only show a preference for face-like stimuli (Rosa Salva et al., 2011; Simion et al., 2011), but also exhibit greater recognition, as indexed through longer gaze time, for faces that have previously spoken to them with direct eye gaze compared to averted faces (Guellai and Streri, 2011). Infants seem particularly attuned to caregiver's *socio-communicative cues*, which include *ostensive cues* designed to grab attention (e.g., direct eye gaze, infant-directed speech), and *referential cues* that function to shift attention (gaze shifts, pointing) to objects and events in their shared physical space. Sensitivity and use of socio-communicative cues are theorized to be the building blocks of social learning and social cognition (Csibra and Gergely, 2006).

Within the first year of their postnatal lives, infants rapidly become sensitive and responsive to socio-communicative cues. Sensitivity to a caregiver's contingent responsivity to infant behaviors, termed *social contingency*, has been observed in infants as young as 3–4 months (Bigelow and DeCoste, 2003; Striano et al., 2005). Between 3 and 5 months of age, infants look longer at objects that their social partner had previously looked at relative to objects that were present, but had not been looked at by their social partner (Striano and Stahl, 2005). By 5–7 months of age, infants shift their attention in response to a social partner's gaze shifts that are accompanied by head turns (Hood et al., 1998; Senju and Csibra, 2008; Woodward, 2003) and then by the end of the first year of their lives, infants reliably follow gaze independently of head movement (Corkum and Moore, 1995; Tomasello et al., 2007). Reddy (2003) argued that a sensitivity to an adult's direct gaze brings about a specific kind of awareness in an infant—that they themselves are the object of another person's attention. In addition, gaze-following has been argued to be a critical component to understanding other people's immediate focus of attention, intentions, emotions, and aids in predicting others' future action and goals (D'Entremont et al., 1997; Farroni et al., 2002; Hood et al., 1998).

By 12 months, infants follow gaze reliably, but their patterns of attention are different from younger infants. For instance, older infants allocate more attention than younger infants to triadic interactions where the object of attention shifts (Woodward, 2003). Woodward (2003) revealed that 12-month-olds, but not younger infants, were sensitive to when an actor changed her focus of

attention to a different object than what she had repeatedly looked at previously. This effect was not observed in 7- to 9-month-old infants. Together, these patterns suggest that 12-month-olds are aware of the relation between a person's gaze and the object of their gaze (i.e., that gaze may reveal information about a person's object preferences). This learned behavior is likely to be a prerequisite to understanding the intentions and mental state of social agents (Woodward, 2003), a prominent theory in the study of social attention and theory of mind (Baron-Cohen, 1991; Charman et al., 2001).

Infants' developing sensitivity and responsivity to caregivers' social cues through the first year of their postnatal lives is argued to be key to the development of joint attention in the second year of life (Corkum and Moore, 1998; Gattis et al., 2020; Moore and Corkum, 1998). *Joint attention* is the coordination of attentional focus of two people on an object or event in their shared space. First, a social partner establishes mutual gaze with the infant, then proceeds to shift their gaze toward an object, and the infant responds by following their partner's gaze to the object (Carpenter et al., 1998; Mundy and Newell, 2007; Scaife and Bruner, 1975). Joint attention episodes are ubiquitous in observation and imitation learning experiments (Mundy and van Hecke, 2008; Slaughter and McConnell, 2003).

In sum, across the first year of their postnatal lives, infants become sensitive to socio-communicative cues from others and the presence of these cues impact infants' attention to, processing of, and learning about their world. These cues also inform infants about their social world—from *when* (e.g., ostensive signals) and *what* (e.g., referential signals) to attend to, to *what to avoid* (see social referencing; Vaillant-Molina and Bahrick, 2012). Through active engagement in social interactions (e.g., joint attention), infants gain an appreciation for social attention and also social cognition, such as the understanding of the intentionality of other's behaviors (Carpenter et al., 1998; Meltzoff and Brooks, 2008). As we discuss in the following section, as infants' experience and knowledge of others grows, so does their awareness that not all social partners provide accurate and reliable information.

Selective social learning

Infants are skilled at learning information provided by social partners and in so doing gain knowledge that they may not have been able to attain on their own, knowledge that is likely to be particularly relevant to the contexts and communities in which they are being raised. However, there are instances in which relying too much on others to acquire information can lead to learning errors or inaccurate assumptions. For example, if an infant places too much weight on learning from their caregivers, they may end up learning incorrect information particularly in contexts in which their caregiver is uncertain or does not possess the most accurate knowledge (e.g., a parent might mis-label an unknown object which could result in a word learning error). Another instance would be infants making the incorrect assumption that certain types of information, such as information about a person's preferences, reflect the preferences of all individuals in their social world. In so doing, infants might be less likely to attend to and learn about the unique aspects of individuals that make them who they are, which may have downstream consequences on their relationships. Thus, not only do infants need to be skilled social learners to acquire knowledge, but they also need to be skilled *selective* social learners.

Contexts of selective learning in infancy

Building on decades of research demonstrating that preschool-aged children are skilled at identifying the situations in which they should prioritize learning information from one individual over another, a substantial body of recent evidence suggests that infants are also selective social learners (for a review see Poulin-Dubois and Brosseau-Liard, 2016). Infants have been shown to adjust their learning in response to informant characteristics that signal when an informant may not be providing information likely to be correct, or relevant to the infant such as an informant's accuracy, competence, and language spoken.

Studies that assess selective learning tend to use a two-informant paradigm modeled from the pioneer study with preschool-aged children conducted by Koenig et al. (2004). Within this paradigm, participants are familiarised with two informants who act on the same object, but in divergent ways. For example, in the original study one informant provided correct labels for familiar objects (e.g., labeled a toy car "a car") while the other informant provided an incorrect label for the same object (e.g., labeled a toy car "a brush"). After familiarization, there was a label training phase in which the informants used different labels to label an object that was unfamiliar to the participant. When participants were later presented with the same unfamiliar object, the key question was whether they would be more likely to attach the label provided by the previously accurate informant to the unfamiliar object than they would the label provided by the previously inaccurate informant. The original findings revealed that, preschool-aged children were more likely to learn the word from the accurate informant suggesting that they used the past information about the informants' accuracy versus inaccuracy to inform their subsequent learning (Koenig et al., 2004). The original paradigm has been adapted for use with infants and, like preschool-aged children, 24-month-olds are more likely to learn novel words from an informant who labeled objects correctly in the past than from an informant who previously labeled objects incorrectly (Koenig and Woodward, 2010; Krogh-Jespersen and Echols, 2012), or used known objects in incorrect ways such as using a toy car to brush their hair (Henderson et al., 2015).

Infants' selective learning has been shown beyond word learning contexts. Within the action imitation domain, 18-month-old infants reproduced non-goal related actions when they were completed by an informant who accurately labeled familiar objects, but not when they were completed by an inaccurate informant (Brooker and Poulin-Dubois, 2013). In this study, infants were more likely to imitate an action that was not directly tied to attaining a goal (e.g., moving an object in a particular manner to its end goal) that had been provided by an informant who had previously labeled objects correctly than they were actions provided by an informant who labeled familiar objects incorrectly. Interestingly, infants were also more likely to help the accurate informant

over the inaccurate informant when both informants were in need, suggesting that selective learning preferences may also extend to selectivity in prosocial behavior (Brooker and Poulin-Dubois, 2013). In addition to labels, infants are also attentive to other behaviors of informants. For instance, infants as young as 14 months of age selectively imitate actions provided by an informant who has used familiar objects correctly (Zmyj et al., 2010) and informants who have been shown to speak the same language as the infant (Buttelmann et al., 2013; but see Howard et al., 2015).

An informant's emotional signals also influence infants' social learning. This was first shown by Chow et al. (2008) using a between-subjects adaptation of the unreliable informant paradigm described above (i.e., Koenig et al., 2004). In this study, 14-month-old infants were familiarized to a reliable informant who had emoted positively toward a box containing a toy or an unreliable informant who had emoted positively toward an empty box. A subsequent gaze following task was used to test how quickly infants in each condition moved to examine the object that the informant had looked toward. The results revealed that infants who had been exposed to a reliable informant were quicker to follow the informant's gaze and explore the object than were infants who had been exposed to an unreliable informant. These findings suggest that infants had learned about the reliability of the informant in the familiarization phase and infants in the unreliable condition had learned that the person was not reliable at signaling when there was something interesting for them to see. In addition to demonstrating another context that highlights infants' selective social learning, these findings contribute to the debate surrounding the nature of infants' gaze following abilities. Rather than supporting infants' gaze following because of an automatic mechanism (e.g., Langton et al., 2000) or a developed sensitivity to contingency (e.g., Moore, 1996), Chow and colleagues' findings suggest that, by 14 months of age, infants' gaze following is supported by their understanding of the referential nature of gaze (i.e., that a person's gaze is goal-directed toward a particular referent and, in turn, socially meaningful).

Building from 14-month-olds' tendency to selectively examine objects attended to by reliable over unreliable informants, by 18 months, infants preferentially imitate actions completed by informants who previously provided reliable emotional signals over actions provided by informants who previously provided unreliable emotional signals (see Chiarella and Poulin-Dubois, 2013 for studies examining infants' selective use of emotional signals).

Even more impressive are the nuances in infants' selective social learning. For example, in a study conducted by Henderson et al. (2015), 24-month-olds learned atypical labels from informants who used familiar objects in atypical ways, but not informants who used familiar objects in typical ways, showing that infants do not simply acquire any information from informants who have been shown to be accurate in the past. Another example of nuanced selective learning in infants comes from a study in which infants showed that they would learn new actions from informants who did not speak the infant's own language in a live face-to-face context, but not a video context (Howard et al., 2015). Interestingly, a follow-up study using the same data revealed that infants' everyday experiences influence their social learning with infants who were being raised in more ethnically diverse (implying linguistic diversity) neighbourhoods being more likely to imitate informants from diverse linguistic groups (Howard et al., 2014). The findings from studies examining selective social learning in infancy reveal that, between 14 and 18 months of age, infants can selectively apply their social learning skills toward informants and contexts in which they are most likely to acquire accurate and relevant information.

Foundations of selective social learning

While selective social learning has yet to be reliably demonstrated in infants younger than 14 months of age, there is robust evidence suggesting that some key foundations likely to support infants' selective social learning are in place before infants' first birthdays. To date, several studies have demonstrated infants' early sensitivity to the varied informant characteristics that have been presented to older infants in selective learning studies. Infants as young as 8 months of age have been shown to be sensitive to information that signals an informant's accuracy. In this study, 8-month-old infants were more likely to visually examine objects that were looked at by an informant who had previously been reliable at looking toward where an object would appear on a screen than they were to examine objects that had been looked at by an unreliable informant (Tummeltshammer et al., 2014). In another series of experiments, 12-month-old infants were more likely to pay attention to informants who played with a set of toys competently (e.g., put bricks in the correct holes and objects away in the correct places) than they were an incompetent informant (e.g., did not put the bricks in the correct holes) (Stenberg, 2013). Informant competence also influenced infants' object-directed play with infants who had been introduced to an unfamiliar and ambiguous toy by the competent informant were more likely to interact with it than were infants who had been introduced to it by the incompetent informant (Stenberg, 2013).

Recently, Bazhydai et al. (2020) developed a paradigm conceptually like the inaccurate informant paradigm described above (Koenig et al., 2004) to test whether 12-month-old infants would actively seek knowledge from an accurate informant over an informant who had explicitly expressed a lack of knowledge (e.g., said "I don't know") in response to the presentation of an object familiar to the infant. Of interest was what infants would later do in an ambiguous context when they were shown two novel objects and asked to find one of them using a novel word (i.e., "Which one is the modi?"). Specifically, the researchers were interested in whether infants would show more signals of social referencing, such as increased visual attention or information-seeking points, toward the knowledgeable informant than toward the ignorant non-informant during this "test phase" of the experiment than during the other phases of the study. The results revealed that infants were more likely to look toward the previously accurate informant than they were the individual who had explicitly declared their lack of knowledge. Young infants' early emerging selective social referencing behavior provides evidence that pre-verbal infants are sensitive to key characteristics of informants that signal whether, or not, they are likely to be useful providers of knowledge. An important question for future research will be to test whether infants' early selective social referencing maps onto their later developing selective social learning.

Another important remaining question involves the psychological mechanisms that support infants' selective social learning abilities, which is a topic of much debate. The potential mechanisms that have been proposed to underlie selective social learning range from higher-order, domain-specific capacities, such as an understanding of theory of mind (e.g., Poulin-Dubois and Brosseau-Liard, 2016), to lower-level non-specialized general learning mechanisms like associative (Heyes, 2017) or statistical (Sobel and Kushnir, 2013) learning. The above findings of the study conducted by Tummeltshammer et al. (2014) reveal that infants' sensitivity to statistical regularities plays a role in infants' statistical learning. However, to date, only one study has directly tested the extent to which infants' statistical learning or developing theory of mind abilities contribute to infants' selective social learning (Crivello et al., 2018). In this study, associations between infants' selective word learning from an accurate or an inaccurate informant and infants' theory of mind and statistical learning abilities were examined. The results supported links between infants' selective learning and their developing theory of mind, but not their statistical learning abilities. Specifically, for infants who were taught novel words by a previously unreliable informant, infants who had more advanced social cognitive skills (i.e., were able to accurately attribute knowledge, or lack thereof, to others) were less likely to learn the words than were infants who had less advanced social cognitive skills (Crivello et al., 2018).

The findings reported by Crivello et al. (2018) were followed-up in a similar study involving a within-subjects design (rather than a between-subjects design) in which 18-month-old infants were exposed to both an accurate and an inaccurate informant and an associative learning task (rather than a statistical learning task) (Crivello et al., 2021). Consistent with their prior work, this study revealed that, when exposed to two informants of differing levels of reliability, infants selectively learned from the previously accurate informant. Further, they revealed that infants with more advanced theory of mind abilities were less likely to learn novel words from an inaccurate speaker. Thus, consistent with prior evidence linking more advanced theory of mind skills and selective social learning in older children (e.g., Brosseau-Liard et al., 2015; DiYanni and Kelemen, 2008; Mills and Elashi, 2014), the findings reported by Crivello and colleagues (Crivello et al., 2018, 2021) support the possibility that the ability to avoid learning new knowledge from informants who may not be providing correct, or socially relevant information, is supported by infants' domain-specific abilities, namely infants' developing theory of mind, and not the domain-general abilities of statistical or associative learning. There is, however, recent evidence suggesting that two other domain-general abilities - infants' causal reasoning and pre-metacognitive awareness—are associated with infants' selective social learning (Kuzyk et al., 2020). Thus, the extent to which infants' selective social learning is driven by domain-general versus domain-specific abilities remains a topic for debate with further research clearly needed to resolve.

Summary

Infants clearly have a variety of tools at their disposal to acquire the foundational knowledge that will support their learning and development beyond infancy. The above findings suggest that learning within the first year of infants' postnatal lives is primarily supported by general learning mechanisms, involving associative and statistical learning. Throughout the second year of life, infants' social learning abilities take center stage. Infants begin to recognize the value of socio-communicative cues, such as a social partner's eye gaze and pointing gestures. As signals they use to acquire information and prioritize such signals over other signals for learning, such as temporal contiguity or salience reviewed in [Associative learning](#) section. This social learning revolution enables infants to expand their knowledge in efficient, yet flexible ways as demonstrated by infants' selective social learning. While existing evidence clearly suggests that infants recruit a range of sources in their everyday lives to learn, what is less clear is how these mechanisms work together to support learning. This is because the decades of research into infants' associative, statistical, and social learning have been quite disparate. As such, the findings supporting different mechanisms tend to suggest that learning is very island based—separate and not connected. However, this is not likely to be the case and does not present a parsimonious view of development. Others have recognized this disparity and have begun to work toward developing unified, integrated frameworks for learning. In the following section we describe some of these approaches.

Moving beyond separate accounts toward integrated frameworks for infant learning

One of the main motivators of research in infant learning is the pursuit of explanations that are necessary and sufficient to explain observed patterns of behavior. Perspectives that emphasize or stress the importance of only one learning mechanism over others do not adequately capture infants' performance across diverse domains of learning, which includes learning words, actions, and about objects which we reviewed in [Learning in infancy](#) section. Further, although researchers often allude to an infant's ability to detect and use statistical regularities that are present in both their physical and social environments, few studies have systematically investigated how associative, statistical, and social learning mechanisms work together to support learning within a single study. In this section, we consider attempts that have been directed toward examining the joint influence of general learning mechanisms, statistical learning, and social learning in infancy.

One noteworthy empirical investigation of the complementary roles that associative and social learning processes play in infants' word learning was conducted by Hollich et al. (2000). In this pioneering, eight-experiment study, word learning was examined in 12- to 24-month-old infants to examine the extent to which infants prioritize different cues and sources of information to identify the correct referent (i.e., meaning) of a novel word across development. The main strength of the experiments described by Hollich et al. was that the same basic paradigm (i.e., the Interactive Intermodal Preferential Looking Paradigm (IIPLP)) was used

systematically to test the age at which infants used associative versus social cues during word learning. While a detailed review of the experiments and their findings is beyond the scope of this article, the results can be summarized easily given the literature reviewed in **Learning in infancy** section. During word learning, infants at 12 months of age placed greater emphasis on cues that support associative learning such as perceptual salience, whereas older infants (between 18- and 24-months of age) placed greater emphasis on using social cues (e.g., informant's eye gaze). However, the results also demonstrated that, while infants placed differential emphasis on associative versus social cues across development, other cues are not ignored. Twelve-month-old infants' word learning was influenced by social cues and 24-month-olds did not disregard perceptual salience as a relevant cue for uncovering word meanings. By demonstrating how multiple learning strategies work in coordination to shape early word learning, this pioneer work opened the discussion for researchers to develop paradigms designed to gain a comprehensive understanding of the ways in which multiple learning mechanisms work together to support learning across the first two years of postnatal life.

While the work of [Hollich et al. \(2000\)](#) enhanced understanding of how different learning strategies come together to support early word learning, their framework does not easily generalize to other learning contexts. However, the work of [Goldstein et al. \(2010\)](#) provides an example of an integrated approach to learning that does. In their article, Goldstein and colleagues recognize that infants outperform models of language learning that are based entirely on statistical learning mechanisms and propose a framework, called ACCESS (Align Candidates, Compare, Evaluate Statistical/Social Significance), which emphasizes how an infant's social context may support statistical learning. Within this framework, infants are viewed not only as excellent pattern recognisers, but as active learners who make inferences and extract meaning from the regularities within their environment. This is where the social context becomes most important.

In the ACCESS model, social partners influence infants' *attention*, which functions to alleviate the processing required through statistical learning, and the *temporal structure*, which binds statistical events across various time windows though consistent, temporally constrained social patterns. Social interactions are behaviorally reinforcing when presented in close temporal proximity to learning experiences, particularly due to their social contingency and high incentive value compared to other non-social reinforcers ([Thiele et al., 2021](#); [Vermetti et al., 2017](#)). For example, caregivers who respond *contingently* to their infant, and whose responses are salient, relevant, and meaningful have an elevated *incentive value* compared to non-social rewards (e.g., dynamic object movement). In the following sections, we elaborate on how social information, present at temporally critical learning experiences, promote learning of associations ([Thiele et al., 2021](#)), hierarchical rule-based learning ([Werchan and Amso, 2020](#)), statistical learning ([Wu et al., 2011](#)) and generalization of learning across contexts ([Werchan and Amso, 2020](#)). In addition, we consider how this framework might apply to domains outside of language learning from which it originated.

Attention

Infants' social partners use of socio-communicative cues, such as eye gaze, function to direct and sustain infants' attention for longer than what would happen in the absence of these cues ([Suarez-Rivera et al., 2019](#)). With age, infants become increasingly sensitive to their social partners' eye gaze. At approximately 14 months of age, infants show sustained attention, particularly during joint attention episodes when caregivers' and infants' attention is coordinated on the same object ([Suarez-Rivera et al., 2019](#); [Yu and Smith, 2016](#)). By 24 months, infants reliably use eye gaze to an object, paired with an object label, to successfully map the label to the object ([Graham et al., 2010](#)). Even more revealing is that [Graham et al. \(2010\)](#) found that performance was dramatically impaired when gaze direction and object labeling were inconsistent. Critically, these cues become more beneficial when the learning environment contains visual distractors that increase ambiguity as to what is relevant to attend to ([Wu et al., 2011](#)), a common occurrence in naturalistic learning settings ([Medina et al., 2011](#)). This observation is echoed in the ACCESS framework, which suggests that social cues from a reliable and knowledgeable partner support learning in distracting environments by narrowing infants' visual attention to that which is most relevant for learning; that is, social attention cues restrict infants' statistical processing to a more focused sample of their environment.

[Wu et al. \(2011\)](#) provide further evidence that social cues enhance infants' statistical learning by influencing infants' attention. In this four-experiment study, 9-month-old infants were repeatedly shown different patterns depicting three novel objects. Critically, two of the objects always appeared together while the third differed across trials. Of interest was how infants used statistical regularities and social cues to learn which two of three shapes co-occurred with one another across contexts that varied in complexity. To test if infants learned the co-occurrence of the two objects during the learning phase, infants were shown two types of test trials: the consistent test trials preserved the association between the two objects that previously co-occurred whereas the inconsistent test trials did not (the two co-occurring objects were shown moving away from one another). The authors hypothesized that if infants learned which objects co-occurred, they would look longer toward the inconsistent test trials that violated their expectations about the objects. The findings of their first experiment were consistent with this expectation confirming that 9-month-olds in their study were sensitive to the co-occurrence of two novel "objects". In subsequent experiments, infants were shown the test trials at the same time (rather than in alternation) thereby introducing distractions to make the task more difficult by increasing the visual attention and processing demands placed on infants. While infants' performance was influenced by the presence of the distractors during the test trials (i.e., infants did not show looking time differences during the test phase with the distractors present), the introduction of an informative social cue (i.e., a face turned toward the pattern showing the co-occurring objects) enhanced infants' performance in the challenging context. Thus, these findings demonstrate the joint utility of statistical and social cues in infants' learning; while 9-month-old infants are sensitive to co-occurring regularities, social cues are helpful in cueing infants' attention in challenging learning contexts.

While informative social cues can support infants' attention and learning, particularly in distracting contexts (Wu et al., 2011), information provided by social sources is not always helpful (as described in **Social learning** section). Xiao et al. (2018) examined whether a social informant's reliability impacts infants' ability to learn cue-object pairings in a statistical learning task. Building on prior work on infants' selective social learning (see Poulin-Dubois and Brosseau-Liard, 2016 for review) and evidence that infants show a same-race-bias (e.g., Quinn et al., 2016; Xiao et al., 2014), Xiao et al. (2018) examined whether 7-month-old infants would use a social informant's race as a cue to guide their learning in uncertain contexts. In a series of experiments, infants were exposed to one of three learning phases where either a same-race or other-race informant provided gaze cues to a location that predicted a target location on 25%, 50% or 100% of the trials. During the test phase, infants' tendency to follow the gaze of each informant without a target appearing was measured. Infants followed the gaze of both informants when their gaze was highly predictable (100%) of target location and neither informants' gaze in low reliability (25%) contexts. However, when an informant's reliability was at 50%, the same-race effect emerged such that infants were more likely to follow the gaze of the same-race informant than they were the other-race informant. This same-race bias suggests that, under challenging learning situations where the probability of the social partner being correct is statistically at chance, infants use prior experience and knowledge to guide their attention and learning.

The above findings demonstrate that in contexts in which it is challenging for infants to extract the statistical patterns present, or if the patterns are unreliable, infants use social information to guide their learning (even information that may not be useful for that specific learning context—e.g., race). Interestingly though, not all social information aids learning. For example, Monroy et al. (2017) investigated statistical learning of action sequences in a sample of 18-month-olds and adults. Participants were presented with a video of two actors who verbally established they were playing a game either cooperatively or in parallel. In both conditions, the actors sat opposite one another, and performed an identical action sequence on a unique set of objects in front of them. The action sequence contained a statistical structure based on transitional probabilities that, if learned, would predict upcoming actions. Participants' anticipatory eye gaze during this phase provided evidence of their initial learning of the sequence. Afterward, participants' memory for the action sequence was tested as they were invited to interact with the objects from the learning phase, both independently and cooperatively with an experimenter. Of interest was whether participants learned better (i.e., were more sensitive to the statistical regularities) in a highly social context (i.e., when the actors were cooperating). Anticipatory eye gaze results revealed that infants and adults correctly predicted action sequences during the learning phase, illustrating they learned the statistical structure of the sequence. While the cooperative context boosted adults' learning relative to the parallel context, infants did not show a learning advantage in the cooperation context. One explanation for the lack of influence of the social context was that the statistical learning of the action sequence was easy to achieve without any social support, like the 100% certainty condition in the Xiao et al. (2018) study. It is also worth noting that the social context did not directly involve the infant, through ostensive (e.g., direct eye gaze) communicative cues, as did other studies described that found an effect of social information on statistical learning (Wu et al., 2011; Xiao et al., 2018). Like the social context in the Monroy et al. (2017), a study by Wu et al. (2014) featured a social but non-ostensive cue condition which failed to facilitate multimodal learning in an attention cuing paradigm. Ostensive cues, however, did promote multimodal learning (Wu et al., 2014), and may be necessary to capture attention and enable the extraction of complex statistical patterns.

This section demonstrates how infants' statistical learning is enhanced by ostensive signals. When statistical learning is made challenging through distractors (Wu et al., 2011) or conditions of uncertainty (Xiao et al., 2018), infants use social cues to enhance their learning of the relevant statistical regularities. In these situations, social cues may resolve ambiguity about who is a relevant source of information and what is to be learned. Further research is needed to better understand how and when infants exploit social information to aid in learning the associations, rules, and statistics present in the environmental inputs they encounter.

Social partners and social contingency

In addition to providing, at a minimum, greater attentional focus and differential processing of to-be-learned objects and events, social cues are embedded within social interactions that have predictable (i.e., statistically reliable) structures. Caregivers have predictable patterns of interacting with their infants across a variety of tasks, such as in their contingent communication, how they teach their infants about objects (Suarez-Rivera et al., 2019; Tamis-LeMonda et al., 2014), and in playing cooperative games such as block building and peekaboo (Bakeman and Adamson, 1984; Duncan and Farley, 1990). Goldstein et al. (2010) argued that these types of social interactions, which are contingent and coordinated with the infant's behavior, serve learning by binding together multiple repetitive patterns across the learning episode and across learning sessions (i.e., over a delayed period). Memory for and detection of the behavioral patterns is thought to aid in the learning of the statistical regularities associated with such social interactions. When considering peekaboo games, caregivers play several rounds of peekaboo in a single play session. During these rounds, caregivers contingently respond to their infant's behavior, which serves to increase infants' attention and engagement in the task. Although caregivers' behaviors have consistency across rounds (e.g., exaggerated speech and infant-directed action aka "motionese"), slight variability in their behavior (e.g., the way they say peekaboo, how they hide themselves, or their accompanying gestures) is theorized to facilitate extraction of regularities across multiple repetitions (Goldstein et al., 2010).

Expanding on the predictability of social partners' behavior during everyday interactions described by Goldstein et al. (2010), caregivers also scaffold learning in predictable ways (Brand et al., 2013; Levine et al., 2019; Yu and Smith, 2012). In a study conducted by Yu and Smith (2012) caregivers labeled objects for 18-month-old infants in a naturalistic setting while infants wore a head-mounted camera and manually explored the objects. Infants then performed a test where the same objects were presented to the infant and named by the experimenter. Better learning, as indicated by infants' looking toward the named objects at test, was associated with episodes during which the caregiver named the object when the infant held the object in the center of their visual field. Interestingly, caregivers tended to name objects when infants were visually focused on the object, suggesting that caregivers are sensitive to this optimal window for infants' learning; that is, when there is most likely to be a one-to-one mapping of label to object.

Given caregiver's sensitivity to optimal learning conditions, it should not come as a surprise that they modify their behaviors when interacting with their infant to draw attention to meaningful boundaries in action sequences (e.g., infant-directed action/ "motionese"), functionally like the effect of infant-directed speech on language learning (Levine et al., 2019). In one study, Brand et al. (2013) examined mothers' scaffolding behaviors while demonstrating a series of action sequences to their 7- and 12-month-old infants. Of particular interest was whether mothers' ostensive, infant-directed gaze occurred more frequently at event boundaries during two object demonstrations. Mothers were given two objects to demonstrate, one object had a set of ordered actions that resulted in a goal (enabling-sequence) while the other did not have a specific order to the action sequence nor an end goal (arbitrary-sequence). Results revealed that mothers conveyed infant-directed gaze cues more regularly at action boundaries. Given the mounting evidence that patterns of reliable social information in naturalistic settings predict upcoming actions (see Levine et al., 2019 for review) and that the availability of social cues in experimentally controlled settings aid in detecting statistical regularities (Wu et al., 2011), more research on the systematic behaviors of caregivers could illuminate *if and how* their predictability benefits learning of statistical input patterns.

Incentive value

In addition to the attentional and temporal cues that social interactions provide which can guide infants' associative and statistical learning, infants also appreciate that social interactions, and the objects associated with social interactions, are inherently meaningful and rewarding. This possibility was recently examined by Thiele et al. (2021) with 13-month-old infants. In this study, infants were presented with a non-social cue (i.e., a green circle or a blue triangle) before being shown a video clip that contained two experimenters who were interacting socially or independently (i.e., completing actions when they were either facing toward or away from one another). The social versus non-social videos were always paired with the same cue and played on the same side of the display, which allowed the researchers to test whether infants were more likely to learn the cue-target association (i.e., side of video) in the social interaction condition. As hypothesized, infants showed enhanced learning of the cue-target association, demonstrated by reduced latencies and anticipatory gaze shifts toward the side on which the video would play after being presented with the cue, for the social interaction condition than they were the nonsocial condition. Critically, the findings were not simply a result of a general tendency for infants to allocate greater attention toward the side of the display that regularly displayed the social interaction. Infants' enhanced cue-target learning in the social condition provides support for the priority that infants place on social interactions as a source of potentially relevant meaningful information, even when infants are simply observing video recordings of a third-party social interaction.

In addition to cue-target associations, infants as young as 8 months use social stimuli to learn hierarchical rule-based structures, which are sensory input patterns that follow specific rules that are generalizable and can be organized into separate rule sets (Werchan et al., 2015). To demonstrate this ability, Werchan and Amso (2021) examined 9-month-old infants' learning of cue-target pairings. In each learning trial, a social attention cue (i.e., a female face presented on a colored background) was paired with a cartoon animation that appeared in one of four locations on a display. The specific face (dark-haired female, light-haired female) and background color (blue, green) combination of the cue corresponded to specific location where the cartoon would play. This design allowed the infant to learn through association (out of four possible person-background color combinations) or by using a hierarchical rule-based structure using either the faces or the background color as the top tier of the hierarchy. Following learning, infants performed one of two generalization conditions, featuring a new set of faces or a new set of colors. The generalization phase was designed to test: (1) whether infants would transfer their initial learning onto a separate set of stimuli and (2) which learning technique (hierarchical with face or color dominant versus associative learning) they employed. The results revealed that infants who were given a new set of faces maintained faster reaction times (visual attention) to target locations compared to infants in the colour-change generalization condition. These findings show that infants formed associations between object properties (such as color) and social information (such as face information) when learning. More importantly, the findings suggest that infants use social information to organize these associations into hierarchical rule-based structures that can be flexibly generalized to new learning sets. Consistent with the findings discussed in Attention section, the authors interpreted their findings to demonstrate that social information guides infants' attention. Critically though, they propose that social information also reinforces learning through the reward system by acquiring incentive value, which has previously been shown to support generalized learning in infants (e.g., Tummeltshammer et al., 2019) and reinforcement learning in preschool-aged children (e.g., Verneti et al., 2017).

Summary

Prior to 12 months, associative, statistical, and social learning mechanisms are available to help infants make sense of the stream of sensory information they encounter. Although infants may be capable of learning solely through a statistical learning approach, for instance, this may not accurately reflect real-world conditions or accurately predict the developmental trajectories of more advanced learning achievements. And in fact, there is now a growing body of evidence of the validity of an integrated approach to understand infant learning (Goldstein et al., 2010; Wu et al., 2011; Xiao et al., 2018).

Following from the concepts outlined in Goldstein et al. (2010) model of learning across time and space, we took a close look at recent studies that tested whether social stimuli would moderate the learning of associations (Thiele et al., 2021), rule-based (Werchan and Amso, 2021) and statistical structures (Wu et al., 2011; Xiao et al., 2018). Empirical evidence suggests that by 9 months, socio-communicative cues capture and direct infants' visual attention to and aid in their learning of hierarchical rule-based structures (Werchan and Amso, 2021) and statistical regularities (Wu et al., 2011). Social cues appear to function to resolve uncertainty about *what* information is most relevant (Wu et al., 2011) or when social agents are unpredictable (Xiao et al., 2018). However, not all social information is equally prioritized. Social but non-ostensive information, as opposed to socio-communicative cues, may support associative learning at 13 months, as a secondary reinforcer with high incentive value (Thiele et al., 2021), but there is no evidence of such information's involvement in more advanced statistical and transfer learning performance (Monroy et al., 2017).

Social cues support attentional systems in their pursuit of patterns of input, but the delivery of social cues is not random or arbitrary. Social partners provide infants with socially contingent, predictable social attention and scaffolding cues (Brand et al., 2013; Levine et al., 2019). Infants are sensitive to these behavioral patterns, and they have been shown to support mapping of labels to objects (Yu and Smith, 2012). Infants may also appreciate and be driven to learn associations and rules based on the reinforcing qualities of social information (Thiele et al., 2021; Werchan and Amso, 2021). However, what we know about the temporal characteristics of naturalistic behavioral patterns of caregivers and their incentive value make investigations into their potential facilitatory effect of statistical or rule-based learning alluring.

Moving forward: research directions, considerations, and conclusions

To date, most of the research surrounding the mechanisms of early learning has focused on studies designed to test infants' learning through isolated mechanisms, or pitting individual mechanisms against one another, rather than looking at how the distinct types of learning work together to support infants' learning across contexts and domains. In Section **Moving beyond separate accounts towards integrated frameworks for infant learning** we introduced two approaches that defy this norm by providing integrative accounts of infant learning that strive to explain infants' learning via general learning mechanisms, such as associative and statistical learning, and social learning mechanisms and processes. One of the most alluring aspects of integrated approaches, such as that proposed by Goldstein et al. (2010), is the promise of capturing infants' learning across diverse contexts in a parsimonious way. With parsimonious integrative frameworks in tow, researchers can design empirical studies to test how infants recruit their diverse set of learning tools to acquire knowledge across domains and modalities. We end by suggesting four broad research areas that we believe would benefit from more integrative frameworks.

First, we propose that researchers could use the Goldstein et al. (2010) framework as a starting point to design studies to examine systematically the statistical regularities present in infants' everyday environments and how these regularities differ across diverse cultural contexts (see Rogoff et al., 2018 for a relevant discussion). The work of Linda Smith and colleagues offers promising avenues to examine these questions (Clerkin et al., 2017; Schroer et al., 2019; Smith et al., 2018; Suanda et al., 2019; Suarez-Rivera et al., 2019; Yu and Smith, 2012, 2016). In their studies, Smith and colleagues attach head-mounted cameras onto infants to capture the regularities in infants' environments from the perspective of the infant. In many of these studies, the infant view is enhanced by recordings from a second head-mounted camera on the caregiver, which allows for caregivers' attentional focus and multi-modal behaviors to also be captured. While this work has been conducted primarily in the USA thus far, recruiting this methodology to study caregiver-infant interactions across the globe will provide invaluable foundational knowledge about the ways in which statistical information combines with social signals and cues in infants' everyday lives to support infants' learning. Given that to date, much of the research on infant learning and the strategies still comes primarily from research groups in Western, Educated, Industrialized, Rich and Democratic (i.e., WEIRD) countries with WEIRD populations (Henrich et al., 2010; Singh et al., 2021), integrated approaches may be the key to moving the field beyond WEIRD studies on infant learning and development.

Second, integrative approaches will also allow for systematic investigations of how different interactive partners in infants' social worlds shape their learning environments and opportunities for learning. As described above, caregivers and infants develop predictable patterns of interacting, which subsequently shape infants' learning (Brand et al., 2013; Levine et al., 2019; Yu and Smith, 2012). One major limitation of much of the work on caregiver behavior and infant-caregiver interactions is the continued focus on mothers even though infants routinely interact with many other social partners in their everyday lives such as a second caregiver at home or caregivers at the early childcare center they attend. Without systematic investigations of the statistical regularities, social cues, and interactive patterns in the range of caregiving contexts infants experience, a complete

understanding of infant learning will elude the field. There has been some prior work demonstrating some ways in which infants (and caregivers) respond differently to different interactive social partners (e.g., Morrison et al., 2021), future work from an integrative framework can examine how variation in expected statistical regularities, or social cues, across caregivers and other social partners influences infants' learning.

Third, one consistently challenging learning task faced by infants is how they generalize or transfer learning from one context to another. Contextual changes are broadly defined; they may refer to a temporal delay between learning and test, or situations in which the physical features of the stimuli or physical learning environment change from learning to test (Barnett and Ceci, 2002). For example, in one study Moser et al. (2015) showed toddlers how to assemble a virtual three-piece puzzle on a 2D touchscreen tablet. Toddlers were then immediately given one of two tests, the same virtual puzzle, or a 3D replica of the virtual puzzle. Toddlers who were tested with the same puzzle pieces that they encountered during the test were significantly more likely to reproduce the goal (to assemble the puzzle) than were toddlers who were given the real puzzle pieces. These generalization or transfer deficits have been studied extensively in screen media learning (dubbed the "video deficit"; Anderson and Pempek, 2005; Barr, 2010; Hipp et al., 2017; Kirkorian et al., 2016), as well as in other domains relating to learning about objects (Woodward and Hoyne, 1999; Wu et al., 2011), language (Maye et al., 2008) and hierarchical rules (Werchan et al., 2015), to name a few. Investigations with integrated approaches may be able to shed a light on how infants may accomplish the transfer problem.

Finally, we encourage researchers to adopt integrative frameworks to describe infants' learning and development beyond the cognitive and language domains focused on in this contribution. In addition to cognitive development, infants make significant strides in their social development throughout the first two years of their lives. By 24 months of age, infants demonstrate at least a basic understanding of goal-directed actions across individual- and shared-goal contexts (for a review see Woodward et al., 2009) and engage in a range of prosocial behaviors (Brownell, 2011, 2016; Hay, 2009). We propose that integrative frameworks that consider the joint contributions of social learning processes and the powerful general learning mechanisms of associative and statistical learning would allow for the generation of complete theories and models of social development. For example, we know from prior work that infants imitate prosocial actions modeled by a social partner (Schuhmacher et al., 2019). Following up on these findings, integrative frameworks could be used to design studies to examine how statistical information of prosocial behaviors might interact with social learning mechanisms to support development of prosocial actions. Or, they can be used to examine whether individual differences in infants' prosocial competencies can be described by variation in the distribution of different exemplars of prosocial actions and the people who engage in such actions in infants' everyday lives.

Here, we have introduced four ways in which integrated approaches will be key to extending understanding of infants' learning and development although there are likely to be many more. We note though that the design of studies taking integrated approaches must be thoughtful and diligent. For instance, researchers need to be mindful of the different behavioral responses that infants might have to ostensive versus non-ostensive cues, or a combination of cues (e.g., infant-directed speech + gaze shift to target; Szufnarowska et al., 2014). It would also be beneficial for adopted paradigms to be appropriate for a wide age-range to enable robust examinations of age-related changes. This is particularly important as we know that infants' attention to, and use of social cues for, learning change across the infancy period (Brooks and Meltzoff, 2005; Mundy et al., 2007; Striano and Stahl, 2005). While designing studies within an integrative framework may have its challenges, for the field to move forward, the questions driving research should no longer be *if* associative, statistical, and social learning shapes learning but should be *how* they come together to promote infants' learning of the knowledge foundations for optimal development.

Introduction

In four short years, newborn infants go from no apparent linguistic competence to mastery of the basics of the language or, in some cases more than one language, that is spoken around them. Apart from extreme atypicality of endowment or environment, all children acquire language. One aim of the study of language development is to understand this universal human achievement. However, children do not all learn at the same rate or reach the same level of proficiency. A second aim of research on language development is to understand the sources of individual differences. Because language is central to most human activity, the individual differences in children's language skills translate to individual differences in school success (Von Stumm et al., 2020) and later life outcomes (Chetty et al., 2010). Thus, the study of language development is both a scientific exploration of human nature and a practical search for the factors that support the fulfillment of human potential.

The core areas of knowledge and skill that children acquire in learning to understand and produce language have been usefully divided by the field of linguistics into four domains: phonology, the lexicon, morphology, and syntax. Phonology is the sound system: each language makes use of a repertoire of speech sounds, with regularities in which differences between sounds signal differences in meaning and regularities in how speech sounds can be combined to form words. The lexicon is the mental repository of word forms and their associated meanings. Morphology is word structure and the regularities in forming words by combining word stems with small, meaningful word pieces such as the sounds that mark a noun as a plural or a verb as past tense. Syntax comprises the system for combining words into meaningful and well-formed sentences. Grammar is typically considered the combination of morphology and syntax, although strictly speaking the regularities in phonological systems are part of grammar as well. When children have mastered these four components (phonology, lexicon, morphology, and syntax), they are considered linguistically competent, but they must also learn to be communicatively competent, which means communicating in socially appropriate ways. Communicative competence includes pragmatic and sociolinguistic competence. Pragmatics is the knowledge of how to

communicate effectively in order to “do things with words” (Austin, 1962; Searle, 1969) such as to make requests, to comment, or to recount narratives. Sociolinguistics concerns the social rules of language use.

This article provides an introduction to the research on language development in the first four years of life that has described the major milestones children achieve in acquiring language and some of the factors that create individual differences in the rate and outcome of those processes.

Major milestones in early language development

The first year: discriminating speech sounds, finding words, and communicating

Discriminating speech sounds

From birth, infants are able to discriminate (i.e., tell the difference between) all speech sounds, or phones, in any language. With experience, infants learn to ignore differences that do not matter. For example, speech sounds differ depending on the other sounds produced before and after them (this is known as coarticulation effects), and sounds are also different when produced by different speakers. These small variations in naturally occurring speech do not disrupt the infant’s ability to recognize the sounds in speech. In laboratory settings, by about 10.5 months of age, infants ignore some aspects of speech variation from unfamiliar speakers to learn new words (Houston and Jusczyk, 2000; Singh et al., 2004). But, in the cases where variation is greater, children’s ability to recognize words is affected. For example, an American English speaker may hear “bowl” when an Australian English speaker produces “ball” (van Heugten and Johnson, 2014). In experimental studies, at 12 months of age but not at 9 months of age, infants are able to recognize words produced in an unfamiliar, regional dialect (Schmale et al., 2010). Only by 13–15 months of age can infants recognize words produced in an unfamiliar, foreign accent (i.e., Spanish-accented English; Best et al., 2009; Schmale and Seidl, 2009; van Heugten and Johnson, 2014). This ability to recognize words in unfamiliar, accented speech increases with age and experience (van Heugten et al., 2015).

The particular sound contrasts that mark meaning distinctions differ somewhat from language to language. As infants gain experience hearing one language, they improve their abilities to discriminate the sound contrasts that language uses and lose the ability to hear sound contrasts that are not used in their language (Kuhl et al., 1992, 2006; Werker and Tees, 1984). This results in the difficulty adult learners of a new language often have in hearing distinctions that are not used in the language they know.

Producing speech sounds

Before infants produce adult-like speech sounds, their vocal productions follow a fairly regular course of pre-speech development. In the first few months of life, infants begin cooing. Coos are vowel-like speech sounds that start as single sounds and eventually develop into multiple vowel-like sounds strung together into one coo. In the next stage, infants incorporate consonant-like sounds to produce marginal babbling. This period of time is sometimes referred to as the period of vocal play (Stark, 1986), as infants try out a variety of sounds that they can produce in combination. Between 6 and 9 months of age, infants produce canonical babbles, which consist of distinct, repeated syllables. This stage of babbling is also described as reduplicated babbling because infants often continuously produce the same consonant-vowel syllables in a series (*mama*). Following this period of reduplicated babbling, non-reduplicated or variegated babbling emerges. In this phase, infants produce sequences of different consonant and vowel pairs—often in long strings that mimic the intonation of adult speech, also termed prosody. This type of babbling is often called jargon, and infants vary widely in how much and for how long they produce jargon (Dore, 1975).

The ability to produce recognizable speech sounds depends, in part, on physical growth of the organs in the mouth and throat that are involved in speech sound production and also on the development of motor control over these articulators. The influence of these biologically paced developments makes some speech sounds earlier developments than others across languages (e.g., /m/ and /d/ are early sounds; /s/ and /θ/ “th” are later acquired sounds). However, the order in which speech sounds are produced is also influenced by the language the children are acquiring (Stokes and Surendran, 2005; van Severen et al., 2013). Children master the production of speech sounds earlier if those sounds are involved in contrasts that distinguish different words in their language (Pye et al., 1987). Most children produce adult-like speech sounds by around 8 years (Hulit and Howard, 2006; Owens, 2006).

Word segmentation

One early challenge in language acquisition is identifying individual words within the speech stream. Even for adults, it is nearly impossible to identify when one word ends and the next begins when listening to natural speech in a completely unfamiliar language. This challenge is made somewhat easier for infants because of the way adults speak to children. Infant- and child-directed speech, sometimes termed motherese or parentese, is a style of speech adopted by parents (and others) when speaking directly to infants and young children. This speech differs from speech addressed to adults. It is slower, clearer, with shorter utterances and longer pauses between utterances, and the pitch is higher (Fernald et al., 1989; Fernald and Simon, 1984; Gerken, 1994). Infants prefer to listen to this speech style over adult-directed speech when given a choice in experimental settings (Carey, 1978; Markman et al., 2003; Mervis and Bertrand, 1994) and are better able to isolate individual words in parentese than in adult-directed speech (Ma et al., 2011). Also, in child-directed speech words are often presented in isolation (Lew-Williams et al., 2011) or with clear intonation differences (Thiessen et al., 2005), and this helps infants find the word boundaries. Once an infant can identify recurring sequences as words, they can start to understand what those words refer to. As early as 6 months of age, children can recognize their names and a few common words (Bergelson and Swingle, 2012; Tincoff and Jusczyk, 1999).

In addition to benefitting from the support provided by features of infant-directed speech, infants make use of statistical learning to identify words. From as young as 5 to 8 months of age, infants are able to learn the statistical regularities in the speech they hear and apply that information to new streams of speech, allowing infants to distinguish frequently occurring sound sequences from infrequent sound sequences. Frequent sound sequences are likely to be single words, whereas infrequent sequences are more likely to include a boundary between different words (Saffran et al., 1996; see Saffran and Kirkham, 2018 for a review of the topic). In addition, infants learn language-specific cues that aid in finding word boundaries. For example, in English, stressed syllables are typically on the onset of a word. With enough experience, by about 9 months of age, English learning infants will learn this regularity and use this as a cue of a new word (Thiessen and Saffran, 2003, 2007).

Beginnings of intentional communication

Infants' first sounds are not considered intentional communication (Bates et al., 1975). Initially, when infants cry, fuss, or smile, these behaviors are reflexive and do not arise from an intent to communicate with others (Oller, 2000). An important milestone in early communicative development is the onset of joint attention. Early in development, infants will attend to objects or to people in their environment, but, by around 9–12 months of age, infants develop the ability to point, gesture, and to share attention with another person. This sharing of attention to a third entity with another person is termed joint attention (Brooks and Meltzoff, 2005), and it is a capacity that sets the stage for language learning. Infants who engage in more joint attention with adults advance faster in developing language (Camaioni and Perucchini, 2003; Carpenter et al., 1998; Mundy et al., 2007). Importantly, children who engage in less joint attention may also hear less speech addressed directly to them, which also affects their language development (Hoff, 2006). We will discuss differences in the home environment leading to individual differences in **The nature of individual differences** section.

By 12 months of age, children point with intention, expecting that an adult will look and engage with the item or direction the infant points (Tomasello et al., 2007). Infants will even point in order to help an adult who is searching for something the infant can see (Tomasello, 2007). The frequency of infants' communicative pointing also predicts their subsequent language development (Camaioni and Perucchini, 2003; Iverson and Goldin-Meadow, 2005; Rowe et al., 2008).

Second year: the vocabulary spurt and the onset of combinatorial speech

The first word and the word spurt

Infants typically have identified the word boundaries in speech, have started to understand the meaning of words, and have used gestures with communicative intent before they produce recognizable speech. Children tend to produce their first word around their first birthday, although the range of variability among children is wide and it is not unusual for first words to appear as early as 10 months and as late as 14 months. The words that children first produce are different from words produced by adults. Adults' words are label for categories (i.e., *duck* refers to all ducks, not just one specific toy duck). For children, the words they first produce may relate to a specific event, game, or item. This label used by children does not necessarily encompass other events, games, or items that would have the same label, and therefore it is considered context-bound (Barrett, 1986; Bloom, 1973; Caselli et al., 1995). With time and experience, words become decontextualized and children start to use the same label for other items or events that share similarities (Barrett, 1986; Bates et al., 1979; Dore et al., 1976). When decontextualizing newly learned words, children may overextend and underextend word meanings. For example, a child may overextend the meaning of "kitty" to mean any four legged, furry pet or they may underextend the meaning of "doggy" to just include their pet but not any dog that passes by them in the park. While these types of speech errors may be very obvious to an adult, they actually do not occur too often in children's speech (Rescorla, 1980) and they may not be due to an inability to understand the meaning of words (Hoek et al., 1986; Hudson and Nelson, 1984; Huttenlocher and Smiley, 1987). Instead, it seems that the child may not know or remember the appropriate label for a referent, and they select the next closest thing in their mental lexicon. In general, each word within the lexicon is an entry that contains some semantic, phonologic, and grammatical information. As a child hears a word for the first time, they store some information about that word. With repeated exposure to that word, in different contexts and with different speakers, children learn the meaning associated with the word as well as the way to produce the word accurately. This description is an oversimplification of a complex process, and there are many theories that discuss how the mental lexicon works, how words are stored, and how words are retrieved for production (see de Sousa and Gabriel, 2015 for a review). The next section discusses in more detail how semantic information is stored within a semantic network.

After a child has produced their first word, more vocabulary follows. By around 18 months of age, children typically have a productive vocabulary of around 50 words (Nelson, 1973). The particular words in a child's vocabulary vary depending on their own experiences (Clark, 1979), but across children, early productive vocabularies tend to be dominated by nouns, with fewer words from other grammatical categories (Caselli et al., 1995; Nelson, 1973). For many, but not all children, the 50-word milestone is followed by a period of rapid lexical growth, termed the word spurt. During this period, children, on average, increase their rate of word learning from around 8–11 words each month to 22–37 words per month (Benedict, 1979). Learning the meaning of a new word often involves an initial fast, but partial, mapping of a meaning onto the word based on the context (Carey, 1978; Markman et al., 2003; Mervis and Bertrand, 1994). With experience, as this new word is heard over and over again in multiple contexts, the meaning becomes more clearly defined (Medina et al., 2011).

Productive vocabulary is not the only type of vocabulary. Children have receptive or comprehension vocabularies, which differ from their expressive or productive vocabularies. As discussed earlier, children start to understand words months before they

produce any and at every age comprehension abilities exceed production abilities. One study of 1803 children found that at 16 months of age, the children understood between 92 and 321 words, but they could produce fewer than 50 words (Fenson et al., 1994).

Building semantic networks

While children are still learning new words, they are also building semantic networks, that is, mental representations in which the words they know are connected based on their shared features. For example, within a category of animals, a golden retriever and a Siamese cat are stored close together due to the meaningful, shared features of those animals: they are both four-legged, household pets, that are covered in fur, and make noises. In contrast, a golden retriever and a parrot, while both animals, share fewer features and therefore are stored farther from each other in the network. In laboratory settings, children at 18 months are quicker to recognize a word when it is preceded by a word from the same category (Arias-Trejo and Plunkett, 2010; Wojcik and Saffran, 2013). This task, called semantic priming, is one piece of evidence of children's early development of semantic networks. Additional evidence comes from children's use of decontextualized nouns, as they tend to overextend to referents that share features (i.e., calling a horse a dog; Moskowitz, 1978). Due to the limited procedures available to measure semantic networks early in development, little is known about these structures in infancy. But by 2 years of age, children are able to demonstrate their ability to use their existing semantic network to learn new words. Two-year-old children learn new words more accurately if the words come from a category in which the children already know more words (i.e., animals) compared to new words from categories in which children know fewer words (i.e., vehicles; Borovsky et al., 2016). At this age, children also learn new words better if those words belong to a category that they are interested in, with interest measured through pupil dilation (Ackermann et al., 2020).

Combining words

After children have produced their first word, their vocabulary grows and they begin to combine those newly learned words. Between 18 and 24 months, children start to put words together in multi-word utterances and eventually, complex sentences (see **First sentences** and **Complex, mult clause utterances** for more details on advanced language structures). First word combinations are termed telegraphic speech because they are typically combinations of nouns or nouns and verbs and do not include grammatical morphemes, a category of word forms including determiners, prepositions, auxiliary verbs, and bound morphemes at the end of nouns and verbs (Brown, 1973). Children may have these words and bound morphemes in their mental lexicons but fail to produce them because of production limitations (Atkinson, 1992; Gerken et al., 1990; Radford, 1990). Children begin to add these grammatical morphemes to their sentences after their first word combinations. Grammatical morphemes are acquired in a similar order across children, and they are reliable components of children's longer and more complex sentences (Brown, 1973).

One feature of children's early use of grammatical morphemes is overregularizations. These errors occur when children overextend a regular pattern (or rule, depending on the theoretical approach one adopts) to words that are exceptions to the pattern or rule (Berman, 1981; Marcus et al., 1992). For example, children may produce *goed*, *runned*, or *eated*. Importantly, the adults that children are receiving input from in their environments are not producing these speech errors. Instead, children are demonstrating that they have learned something about the regularities in language (Marcus et al., 1992).

Expanding communicative purposes

By 2 years of age, most children produce multi-word utterances to serve a variety of communicative purposes. As vocabulary and morphosyntactic knowledge continue to grow, the range of purposes to which children put their speech and the range of topics children talk about also develop. Children learn the pragmatics of conversations: how turn taking works, how to initiate a new topic of conversation, and how to repair a miscommunication (Bloom et al., 1976). Children start by talking mostly about the here-and-now, and conversations are sustained largely by the efforts of the adults involved (Snow, 1977). Early conversations are typically short, due to children's limited attention, but frequent, as children find new topics to discuss easily (Nelson, 1996).

From 24 to 36 months: mastering grammar and developing discourse skills

First sentences

Children's first sentences tend to be very simple sentences that involve one verb and take on three general forms: an imperative sentence, (a command), a declarative sentence (a statement or explanation), or a question. At first, children use mostly imperative sentence structures, followed by declarative sentences, and then questions, which are used more frequently as children develop (Vasilyeva et al., 2008).

Children also produce negative statements from an early age, but the form of those statements is not initially adult-like. In English, it is typical to use an auxiliary verb in order to express a negative statement (e.g., *I do not want to go*), and that auxiliary (*do*) is inserted between the subject and verb. When children first produce negatives they tend to put the negative marker outside the sentence (e.g., *No want go*) followed by putting the negative marker inside the sentence (e.g., *I no want go*; Klima and Bellugi, 1966). Children's first question forms also differ from the adult forms. Children will initially ask questions through intonation alone. With time, they will start to add *wh*-words to their questions (*What that is?*). By the time children are around 4 years of age, negative statements and questions contain the appropriate auxiliaries and children sound adult-like in their sentence structure.

The development of conversation and narrative skill

Between the ages of 2 and 3 years, children's conversation skills develop. Children start to talk about past events (Adamson and Bakeman, 2006) and they start to produce their first narratives (Eisenberg, 1985; Reese and Fivush, 1993). These are typically prompted by adults who may ask follow-up questions to encourage the continuation of the narrative, a technique called scaffolding (Clarke-Stewart and Beck, 1999). While narrative topics vary depending on the interests and experiences of the child (Miller et al., 1993; Nelson, 2004), these narratives are just a first step in their development. With time and experience, children come to produce more complex, cohesive narratives (Karmiloff-Smith, 1986) and their ability to produce narratives will aid them in their later academic language (Snow and Uccelli, 2009) and literacy development (Snow and Dickinson, 1990).

After the third birthday: further developing skills

Complex, mult clause utterances

After children produce their first multiword utterances, their utterances grow in length and complexity. Sentences may include multiple verbs, or clauses. Children begin using these more complex structures once they start producing utterances with four words (Bowerman, 1976). Between 2 and 3 years of age, the use of these sentences increases (Bloom, 1991), and children produce an adult-like range of complex sentence forms by about 4 years of age (Bowerman, 1979; Limber, 1973).

Continued growth and influences from schooling

By the age of 4 years, children have acquired the foundational skills necessary for linguistic proficiency. They will continue to develop their competencies in all domains of language. When children begin formal schooling, they will face a period of transition as they learn to adapt to a new environment. This new environment includes influences from social interactions with their teachers and peers, and also the start of literacy instruction. Many of the skills children learned before school will aid them in their later reading achievement.

Individual differences in early language development

The nature of individual differences

In broad outline, typically developing children follow similar paths in acquiring language. In production, infants first coo then babble, and then produce their first words, which tend to be produced in single-word utterances. Next, children put words together, and then their utterances grow longer, and the grammatical complexity of those utterances increases. Both the sequence and timing of these major milestones of language development—canonical babbling, first words, and first word combinations—appears fairly constant across children and environments (Casillas et al., 2020), and all typically developing children achieve these milestones. In contrast, the rate at which children add new words to their vocabularies and increase the grammatical complexity of their speech varies widely, and even among adults there is substantial variability in vocabulary knowledge and the grammatical complexity of speech (Hoff, 2006).

Internal sources of individual differences

Some of the variability among children in the rate of language growth is a function of individual differences in language learning abilities. Abilities that have been found to predict language growth include the following: the gaze of speakers and sustaining joint attention (Brooks and Meltzoff, 2008), short term phonological memory (Gathercole, 2006), a variety of attention and related skills that fall under the umbrella of executive function (Gandolfi and Viterbori, 2020; Kapa and Colombo, 2014; Ronfard et al., 2021), and statistical learning (Kidd, 2012; Kidd and Arciuli, 2016). These language learning skills may themselves develop with time and experience, but there is good evidence of a strong genetic component to language acquisition as well (Dale et al., 2000; Stromswold, 2001).

External sources of individual differences

The rate at which children grow in the size of their vocabularies and the range of grammatical structures that they use and understand depends substantially on the quantity and quality of their language exposure. The effects of quantity are easy to describe: children who are talked to more develop language more rapidly than children who are talked to less (Hart and Risley, 1995; Huttenlocher et al., 1991). But not all speech that children hear is equally useful to them in building language knowledge. Children who hear many different words build vocabularies faster than children who hear fewer words (Hoff, 2003; Hoff and Naigles, 2002). This effect holds within grammatical categories: children who hear many different verbs as the main verb in sentences subsequently use a larger verb vocabulary in their own speech (Hsu et al., 2017).

Hearing a varied vocabulary also helps children learn aspects of grammar. Children who hear many different nouns used as the subject of sentences learn that verbs take different endings depending on whether the subject is singular or plural (e.g., *the girl walks* but *the girls walk*) at an earlier age than children who hear fewer nouns as sentence subjects (Hadley et al., 2017). Children also benefit from syntactic complexity in input. The length of the utterances mothers address to their children predicts their children's

subsequent vocabulary growth (Hoff, 2003), and the diversity of syntactic structures in the speech addressed to children predicts the diversity of structures children come to use in their own speech (Huttenlocher et al., 2010). Apart from properties of the speech children hear, children's language development also benefits when their conversational partners are responsive to their speech and early vocalizations (Tamis-LeMonda et al., 2001), and expressive language skills also develop more rapidly when the children, themselves, contribute to conversations (Donnelly and Kidd, 2021).

The social context and language development

Children who grow up in different circumstances may have very different language learning experiences and their language development may also differ as a result (Hoff, 2006). One important field of research is aimed at describing the both the variability and the commonalities in children's language learning experiences worldwide, and the relation of the variability that exists to children's language development (e.g., Hoff, 2006; Rowe and Weisleder, 2020). Here we review the impact of two social context variables that shape language experience and language growth for many children: socioeconomic status and exposure to multilingual environments.

Socioeconomic status and language development

The quantity and quality of speech children hear varies as a function of their families' socioeconomic status (SES; Hoff and Laursen, 2019), with consequences for the children's language development (Hoff, 2006, 2013). This was dramatically and famously documented by Hart and Risley (1995), who recorded the speech addressed to children from different socioeconomic strata on a monthly basis from the time the children were 9 months old through the age of 3 years. Based on the number of words children heard per hour in those recordings, Hart and Risley (1995) calculated that by the age of 4 years, children from low SES homes will have heard 30 million fewer words than children from high SES homes. This gap in linguistic experience, often called the word gap, is present not only in the quantity of speech that children hear, but also in the quality of speech they hear. Many other studies have found SES-related differences in the richness of the vocabulary and diversity of grammatical structures children hear in the speech addressed to them (Golinkoff et al., 2019; Hoff, 2013; Huttenlocher et al., 2010). The purposes of adult talk have also been found to differ as a function of SES. Compared to higher SES mothers, lower SES mothers more frequently address their children in order to direct their behavior and less frequently talk to their children for the purpose of engaging them in conversation (Hoff, 2006; Hoff and Laursen, 2019).

Children from low SES households differ from children from higher SES households in having smaller vocabularies, shorter utterances, and a more restricted range of grammatical structures (Arriaga et al., 1998; Hart and Risley, 1995; Huttenlocher et al., 2010; Snow, 1999), although the findings with respect to grammar are less robust than the gap in vocabulary skill (Hoff and Tian, 2005; Noble et al., 2005). The differences in children's language skill associated with SES can be linked to the differences in child-directed speech that are associated with SES (Hoff, 2003; Huttenlocher et al., 2010). By school entry, children from low-income households are less able to produce effective communicative messages (Lloyd et al., 1998). In addition, children from low-income households have less sophisticated narratives (Vernon-Feagan et al., 2001), limited phonological awareness skill (Lonigan et al., 1998; McDowell et al., 2007), and are slower in accessing known words (Fernald and Marchman, 2012).

Multilingual exposure and language development

Many children are exposed to more than one language in early childhood, and multilingual exposure creates additional variability in the quantity and quality of children's language exposure. The most obvious effect on experience is that the quantity of children's exposure to each language is, on average, less than it would be if they were hearing only one language. In the early stages of development, bilingually developing children acquire each of their languages at a slower pace than monolingual children acquire their single language, and the relative amount of time children hear each language is a significant predictor of their rates of growth in each language (Hoff et al., 2012; Hoff and Ribot, 2017). When knowledge in their two languages is counted together, it is clear that bilingual children are acquiring language at a comparable pace to monolingual children (Hoff et al., 2012). The lag in the rate of development compared to monolinguals reflects the fact that their experience and therefore their growth is distributed across two languages. If children continue to receive high levels of high-quality exposure to two languages, the evidence suggests bilingual children catch up to monolingual children for all practical purposes. However, many of the real world circumstances in which children are exposed to two languages advantage one language over the other.

For example, when one language is used only at home, the range of vocabulary and grammar the children are exposed to may be less than for the language that the children also use in school. As a result, children in immigrant families often end up with stronger skills in the language of their new country and school than in the language they first heard from their parents (Giguere and Hoff, 2020). Children in bilingual or multilingual environments also often hear a great deal of speech from nonnative speakers (Place and Hoff, 2011, 2016). The proficiency of nonnative speakers influences the quality of their child-directed speech (Hoff et al., 2020). The difference in quality of speech by non-native parents with lower proficiencies impacts children's vocabulary development (Buac et al., 2014). This impact can be lessened when one parent is a native speaker of the target language (Hoff et al., 2014, 2018; Place and Hoff, 2011).

Maternal education, which is one of the indicators of SES that is reliably associated with both the quantity and quality of child-directed speech and with children's language development in monolingual samples (Hoff, 2003; Rowe, 2008, 2012) is a more complicated variable for bilingual mothers—and fathers. Many bilingual parents are immigrants who attended school both before immigration—in their native language—and after immigration—in the language of their new country. Some research suggests that maternal education has language-specific effects on language use in the home and on children's language growth. In a sample of bilingual mothers in Canada who varied in their first language, those who were more educated in English (their second language) spoke English more often to their children (Duncan and Paradis, 2020). Among Spanish-English bilinguals, maternal education in Spanish predicted children's expressive vocabulary growth in Spanish, but not English, whereas the education level they achieved in English predicted the children's English vocabulary and not their Spanish vocabulary (Hoff et al., 2018).

Because language learning experiences can be so varied in multilingual environments, bilingual and multilingual speakers vary widely in their language skills—in childhood (Hoff et al., 2021) and in adulthood as well (Luk and Bialystok, 2013). Bilingual children who attend school in one of their languages tend to achieve monolingual-like levels of proficiency in that language (Giguere and Hoff, 2020), but even early exposure does not guarantee development of a language that is only a home language (Ardila et al., 2019; DeHouwer, 2007; Giguere and Hoff, 2020).

Summary and conclusion

Language is a universal characteristic of the human species and language acquisition a universal aspect of early development. Language development follows a fairly regular course across children. In this article we have provided a broad overview of that course of development in first four years of life. We have described the changes in what children are able to produce and the communicate purposes to which they put their growing linguistic abilities. We have described some of the individual differences observed in language development, and we have said something about the sources of those individual differences.

The list of topics that we have not covered in this article is long. We have said little about the processes underlying the child's acquisition of language, and, accordingly, little about the theoretical controversies in the field. We have ended our description at 4 years and not discussed later developments in oral language nor the acquisition of literacy. Our description is based largely on studies of typically developing, monolingual children acquiring English in mainstream North American families. We have said little about children with atypical abilities and little about the acquisition of other languages or language acquisition in other cultures. We invite the interested reader to pursue these and other topics in the in the suggested further readings.

Introduction

Early childhood education (ECE) is informed by a range of ideas, philosophies and theories, which have developed over time and in different national contexts (Gunn and Nuttall, 2019). These diverse influences have been mystical, spiritual, ideological and pragmatic, based on contrasting ways of understanding children and childhood. From the middle of the nineteenth century the early childhood "tradition" or "inheritance" created a blueprint for the dominance of Euro-American theories in driving changes in society's perceptions of children's need for free play, education and care, and understanding childhood as a distinctive period of human development. The different approaches that emerged from this tradition combined beliefs about how children should be treated in society, and how they learn and develop. Governmental and societal concerns for children's health, welfare and education required a scientific approach to justifying public investment. Hence the philosophical and ideological orientations of the "early pioneers" of the nineteenth century gave way to the new discipline of child study, with educational and child psychology bringing methods and theories from the learning sciences. How these theories were interpreted during the twentieth century emphasized the child's natural/biological development, and created a maturational narrative of learning and development progressing through ages and stages, with children needing to become ready to progress from one stage to another. In the field of practice, the work of influential psychologists such as Susan Isaacs and Jean Piaget, and the educational philosopher, John Dewey, was aligned with progressive principles of child-centered education, which emphasized hands-on experience, and active learning through play, exploration, inquiry and discovery. The expansion of provision for children before compulsory education, and guidance for practice, were thus informed by a complex inter-relationship between the learning sciences and educational reform. Developmental and educational psychology subsequently provided the dominant theoretical orientation to educating ECE teachers and practitioners, and informing practice, alongside enduring but often uncritical commitments to the sedimented knowledge from the early childhood "tradition."

Shaping children's development through home, community and education contexts reflected socio-economic shifts toward shared responsibilities between private (family) life, and public (state) investment in ECE. As Wood (2020) argued, child development theories appealed to this dual economic-education rationale because they provided a scientific basis for child-rearing, child-care and health, and presented development as hierarchical, regular, and linear. The influence of the learning sciences on ECE led to the adoption of the Piagetian theoretical orientation that development leads or precedes learning through biological maturation, and social interaction. Drawing on research conducted primarily in the USA and western European countries, early childhood educators responded to the powerful discourse of "developmentally appropriate practice" (DAP), which, from the 1980s, secured international reach and impact (NAEYC.org/DAP) (National Association for the Education of Young Children, 2020). Educational programs informed by DAP were based on the child's observed trajectory, and mapped against developmental goals, organized into the developmental domains or areas of learning.

When integrated into educational approaches, and ECE policy frameworks, child development theories have created a regime of truth (Bartholomaeus, 2016) based on typical expectations, goals or milestones. The tendency toward "normalization" results in children being positioned as normal/abnormal, achieving/underachieving, being typical or ahead, or lagging behind (Wood, 2020). These forms of labeling influence how children (as groups or individuals) are positioned as being "at risk," "developmentally delayed" and "in need" of interventions. A core problem of conceiving development in an "ages and stages" model is that developmental processes are not consistently hierarchical, causal or deterministic: transitions vary in their timing, and different approaches to learning are situated in different socio-cultural-historical contexts (Chen et al., 2011; Gutiérrez and Rogoff, 2003). Contemporary interpretations of socio-cultural theories provide contrasting perspectives on learning and development, with potential for responding to changing societal and global challenges.

The work of the Russian psychologist, Lev Vygotsky was revolutionary in its own time, and laid the foundations for new ways of thinking about human development that contest "ages and stages," and illuminate complexity. It is important to emphasize that

Vygotsky laid the foundations, because his theories and research were still in development when he died in 1934 at the age of 37. Following translations of his work into English, Vygotsky's theories were subsequently developed posthumously, and have been contested and reinterpreted by different people, through a range of disciplines, and in different socio-cultural contexts, from early childhood, across the lifespan. Contemporary socio-cultural theories may be post-Vygotskian, or neo-Vygotskian, but generally trace their origins, and subsequent interpretations to his original works, and identify what omissions have been addressed (Bruner, 1996; Daniels, 2008, 2016; Newman and Holzman, 2013; Rogoff, 2003). New insights have been developed through empirical research, drawing on inter-disciplinary perspectives, for example in play (Holzman, 2017; Sutton-Smith, 1997; Wood, 2013), and learning (Chesworth and Hedges, 2023; Hedges, 2021; Lenz-Taguchi, 2010). A key theoretical shift, as argued by Hatch (2010, 2012) and Holzman (2017), is that learning leads development, with learning and development being in dialectical relationship. This shift contests the epistemological hierarchy of child development theories, informed by global perspectives and contemporary critique and interpretations of socio-cultural theories (Hedges, 2022; Stagg Peterson and Friedrich, 2022; Vintimilla and Pacini-Ketchabaw, 2020).

The aim of this chapter is not to critique or analyze different interpretations of socio-cultural theories, but to examine the implications of selected key concepts for the policies, purposes and practices of early childhood education. This chapter addresses three key questions.

1. How have socio-cultural theories developed over time?
2. What key concepts are informing early childhood education?
3. What are the implications for early childhood education: from developmentally to culturally appropriate practice

Section 1: How have socio-cultural theories developed over time? provides an overview of the development of socio-cultural theories, drawing on the work of Lev Vygotsky. **Section 2: What key concepts are informing early childhood education?** examines three key concepts that derive from Vygotsky's original work, and the different ways in which these have been developed and interpreted in ECE. The three concepts are learning leading development; cultural tools and symbol systems (tools for use/tools and use) and children's agency and motivation. **Section 2: What key concepts are informing early childhood education?** elaborates the selected concepts in relation to contemporary understanding of play as a leading activity in ECE, and play as social practice. **Play as social practice** considers the implications for early childhood education of contemporary interpretations of socio-cultural theories, specifically the conceptual reorientation from developmentally to culturally appropriate practice, and to learning leading development.

Section 1: How have socio-cultural theories developed over time?

Socio-cultural theories provided a conceptual shift toward understanding human development and learning as dialectical, socially- and culturally-situated, drawing on contemporary practices, and those of previous generations, hence the cultural-historical focus (Rogoff, 2003; Rogoff et al., 2018). In ECE, socio-cultural theories have moved attention from what is developmentally appropriate to what is culturally appropriate, so that diversity and difference are understood within children's everyday social and cultural practices in their homes, families and communities. Contemporary interpretations are linked to wider debates about global knowledge and policy flows, and the global politics of knowing, learning and teaching. The focus on the cultural nature of human development provokes critical engagement with inclusion, equity and equality, and the policies, purposes and practices of ECE.

For Vygotsky (1978), learning is a social process, situated in socio-cultural/cultural-historical contexts. This foundational concept informs the contemporary emphasis on co-construction as peers and adults engage and participate in shared practices. Children's learning happens within developmental environments, or interrelated systems (Darling-Hammond et al., 2020) that are organized to promote learning and teaching. In ECE, the developmental domains are interrelated—physical/emodied, social/relational, emotion/affect, psychological/cognitive. The subject areas or disciplines are understood as cultural tools and symbol systems, including their distinctive skills and concepts, and ways of thinking, inquiring, creating and problem solving. Engagement with the subject disciplines, whether in everyday/emergent, or scientific forms, is transformative in that children participate with increased competence, agency and sense of identity. The social situation for development promotes engagement and participation with humans and non-humans, cultural tools, materials, symbols, technologies, the natural world, and valued knowledge. The term “valued knowledge” is understood from a socio-cultural perspective as contextually situated, drawing on children's cultural repertoires, languages, interests and shared knowledge in their homes, families, communities and education settings, including popular culture and digital media. For example, in children's social play, knowledge that is valued and useful includes knowing how to join a play episode, how to contribute imaginative ideas that develop the play theme and events, and how to keep the play going by taking turns, sharing and listening. Different forms of “valued knowledge” are also inscribed in ECE policy and curriculum frameworks.

Knowledge is not acquired “in the brain,” but is co-constructed in social contexts through distributed social practices that involve using concepts and cultural tools with purpose and meaning. Learning over time is not simply a matter of “acquisition”—learning, remembering or knowing more. In their everyday activities, children are capable of co-creating their own interests and purposes, drawing on available cultural tools and resources, co-constructing meaning, and producing outcomes that are relevant in the moment, and build toward further learning. These processes lead to the transformation of participation (Rogoff, 2003; Rogoff et al., 2018): as learners become more skillful, competent, knowledgeable and confident, they take responsibility for assuming

active roles in the management and development of activities. They progress toward deeper engagement in communities of practice as they develop their identities, and their agency.

Section 2: What key concepts are informing early childhood education?

Learning leads development

How we understand learning and development has implications for children's education, care, health and well-being, and their rights. As noted earlier, a key socio-cultural perspective is that learning leads development, with learning and development being in dialectical relationship (Hatch, 2010, 2012; Hedges, 2022; Holzman, 2017). Children are not "adults-in-waiting"; they have their own complex ways of being, becoming and belonging, making meaning, and coming to know in their homes and communities, and the distinctive social contexts of ECE settings. Taking a learning leads development perspective respects diversity and difference, and responds to children's agency and participation in social contexts. Key themes (such as play) and concepts (such as the zone of proximal development) have been particularly influential in ECE, again with contrasting interpretations and emphases.

The zone of proximal development

Vygotsky's original writing about the zone of proximal development (ZPD) has been re-interpreted, including different translations of his theories and meanings, with different implications for research and practice (Daniels, 2008, 2016; Hill and Wood, 2019). Although Vygotsky (1978) proposed critical periods and crises in development, these were not structured into defined ages and stages. For Vygotsky (1978) learning and development are interrelated from birth, but learning leads development within the zone of proximal development.

It is worth remembering that the ZPD was a conceptual tool through which educators and psychologists could understand the internal course of development as a social-cultural-historical process. The ZPD is also a metaphor, to conceptualize the distance between actual and potential development, and how development occurs collectively through guidance or collaboration with more or differently capable humans—adults or peers, with the support of cultural tools. Vygotsky proposed a dialectical relationship between a child's actual and potential level of development, as evident in what a child can do unaided, and with support. He used the metaphor of the "buds" or flowers' and the "fruits" of development (1978, p. 86) to explain dynamic processes of change:

... an essential feature of learning is that it creates the zone of proximal development, that is, learning awakens a variety of internal developmental processes that are able to operate only when a child is interacting with people in his environment and in cooperation with his peers (1978, p. 90).

The concept of the ZPD draws attention to the quality of the social situation for development, specifically the developmental potential of the environment. The processes of mediation involve children making meaning through cultural tools, symbol systems and materials, drawing on their own motives and agency. Taking a learning-leading-development perspective, Holzman (2017, p. 29) understands the ZPD as a collective form of working together and argues for emotionality to be considered along with the traditional emphasis on cognition. Holzman (2017, p. 121) further argues that if we accept the ZPD as a "life space in which and how we all live, inseparable from the we who produce it, then explanations for how child and world are "connected" are not needed." From contemporary perspectives, the ZPD might equally be understood as a zone for potential learning.

In ECE, the ZPD been interpreted as a pedagogical zone where the teacher/adult (often positioned as the more knowledgeable other) supports a child, or children to learn specific skills, behaviors or concepts. Pedagogical strategies include direct, systematic instruction, as well as guided participation, scaffolding, intersubjectivity, and co-playing. Activities may be formal/structured or informal and open-ended, and are typically organized via learning centers to direct children's engagement with specific materials and concepts (for example in Literacy, Mathematics, Science), or providing space, resources and time for freely-chosen play. However, understanding the ZPD as a pedagogical zone demands attention to who, and what is in the ZPD, and raises questions about who decides what is "proximal" for an individual child, or group, and what is the further potential or direction of development or learning in the activity? In an adult-directed pedagogical activity, the adult may decide the object of the activity - what is proximal for the child or group. In many countries, early childhood educators are likely to be using curriculum frameworks that act as cultural tools to describe or prescribe learning goals, and structure the course of learning and development over time. In child-led activities, children co-construct events and experiences that draw on different proximities and motives, creating a mash-up of knowledges, skills, languages and cultural repertoires. Contemporary interpretations of the ZPD question the much-used mantra that learning must always start from the child, and must be in alignment with the current level of development (which is usually determined at an individual-developmental level). Such a starting point does not acknowledge the potential for collective creativity, or children's collective agency in influencing their learning and development, even where the next steps may lie at the limits of their capabilities. Learning that "starts from the child" but without challenge is likely to leave children where they started, and may not provide the participation, engagement and motivation needed to realize potential. In the context of play, "starting from the child" demands attention to the imaginative qualities of play where children may be drawing on diverse sources of knowledge and interests (including popular culture, home and family practices) that are not always visible to adults in ECE settings.

A key theoretical challenge in ECE is to understand how children progress in their knowledge, skills and understanding. From a Piagetian perspective, progression is linear - from simple to complex, or “mature” forms of thinking and action. As noted previously, theories about children’s development progressing through “ages and stages” have proved appealing to policy makers in designing curriculum frameworks and organizing goals in linear sequences. In contrast, socio-cultural theories problematize progression as continuous emergence from everyday to scientific (discipline-based) concepts, with pedagogical support, as children engage in contexts and shared activities with different forms of complexity. Contemporary understanding of emergence supports the proposal that learning leads development, which, as [Hatch \(2010\)](#) argues, provokes different theoretical questions, and has different implications for practice. Everyday concepts can be seen as emergent, naive or intuitive, and scientific concepts are more highly structured and developed. For example, mathematics provides the conceptual tools for children to count, order, organize, estimate, measure, share and divide. However, the power of those concepts is realized as children use and apply them in different contexts, showing a co-relationship between everyday and scientific concepts. Being and becoming a mathematician is about the inter- and intra-subjective experience of being in a world that can be understood, organized and expressed in mathematical ways, and enables children to create and solve problems with a variety of tools.

Whether we look at the creative arts, sciences or humanities, within developmental environments, or interrelated systems, there is no “end point” of development, and no fixed definition of “mature” thought or specification of “higher mental processes.” For [Rogoff \(2003\)](#) development occurs when the balance of power shifts toward the learner as they take increasing management of, and responsibility for, activities. It is here that the transformative potential of learning is experienced as an ongoing and cumulative process. If there is no end point of learning or development, then specifying “outcomes” at a certain age (such as the transition from pre-school to compulsory schooling) is more to do with the socio-political framing of education, and the specification of curriculum goals in policy frameworks.

If the ZPD is interpreted as a metaphor for understanding the potential of human development ([Holzman, 2017](#)), there are implications for understanding the dialectical relationship between cultural tools and symbol systems, materials and resources, relationships and interactions, and the pedagogical or relational strategies that are used by more or differently knowledgeable others (not just “teachers”). These “others” may be human—peers and adults, and non-human, including material, digital, spatial, physical and virtual resources.

Cultural tools and symbol systems (tools for use/tools and use)

Understanding learning as a socio-culturally mediated process, [Holzman \(2017\)](#) discusses the Vygotskian concept of tools for use/tools and use, and the role of tools in creative and transformative activity. Children learn to think and act with and through cultural tools and symbol systems, with language/languages at the center of understanding and making meaning. In contemporary contexts, the “more” or “differently” knowledgeable other can be physical or virtual, including cultural tools such as the internet, Apps and social media. The meditational role of tools (tools for use), and the meanings children ascribe to them (tools and use), motivate activity, including how they communicate and participate in different contexts, often with imagination and creativity.

Vygotsky proposed a dynamic interaction between thought and language (or thinking and speech) that combines inter- and intra-individual cognitive and social processes. For example, as children collectively play and learn together, they combine individual and shared communicative repertoires. They remember, plan, organize and reflect, so that cognitive and meta-cognitive development is distributed across people, places, experiences, events and materials. These are the means by which cognition in use and in social interaction becomes internalized, appearing, in Vygotskian terms, first on the social and then on an individual plane. Contemporary research understands language, and languages, as more than grammar (syntax, morphology, phonology and semantics). Children’s communicative practices are multi-modal, including speech, physical gestures, musicality, movement, facial expressions, drawings, constructions, signs and symbols (including sign languages). In multi-diverse societies, many children are growing up as bi- and multilingual, which shifts attention from the dominant culture and language of the classroom, school and wider society, to shared knowledge of many cultures and languages.

Socio-cultural theories have been re-contextualized in the context of super-diverse, multi-lingual societies, with attention to the power relationships in children’s lives. Questions about what is culturally appropriate include concerns with power relationships, and critical engagement with social structures and systems. Research by [Tatham-Fashanu \(2021\)](#) focused on mono- and multi-lingual children, aged 4–5 in a primary school in England, to examine how they established and experimented with their individual identities through their language choices. Combining socio-cultural and post-structural perspectives, Fashanu challenged dominant language discourses, specifically the way in which “English-only” was promoted as a means of engaging the children in language learning, de-valuing their home and community languages. Using ethnographic methods, many instances of children subverting or contesting this dominant discourse were recorded, notably during lunchtime, and free play and free choice activities ([Fashanu et al., 2020](#)). Children were observed using their home languages, and explaining the meanings of words or phrases to their peers. The children were skilfully navigating the space, subverting the rules, and establishing their own linguistic identities and repertoires. The research reveals how dialectical relationships between the individual/social are infused with power dynamics, where children find ways of resisting rules imposed by adults, and find spaces in which to exercise agency and participate in social practices that are transformative on their own terms.

Technological innovations have brought about transformative changes in play, work and leisure, with implications for understanding children’s motives and agency in learning and development, and for disrupting institutional and inter-personal power relationships ([Erstad et al., 2017](#)). The uptake and use of digital technologies has been rapid, motivated by touchscreen technologies,

which were designed from the outset to be accessible for young children, and to offer new potential for creativity and multi-modality. There are no “developmental pathways” to prescribe children’s engagement with digital technologies. The concept of convergence (including converged or connected play) explains how digital technologies have blurred the boundaries between formal and informal contexts for learning, physical/virtual, traditional/digital, online/offline, place/space, play/work, and between children as novices and adults as experts (Marsh, 2017; Edwards et al., 2020). From the perspective of convergence, children’s engagement with digital technologies (as tools for use) exemplifies learning leading development: children acting with technologies (tools and use) are motivated to create different possibilities and trajectories for learning and development, based on multi-modal communicative and digital literacy practices.

Interpreted as a collective potential space, the concept of the ZPD opens possibilities for understanding children’s emergent ways of thinking, making meaning and coming to know. In contemporary interpretations of the ZPD, children are active participants in shaping and mediating their own developmental environments, in collaboration with cultural tools and symbols systems. Respecting children as active participants raises concerns with power relationships, and children’s agency and motivation.

Children’s agency and motivation

From a socio-cultural perspective, human beings are agentic because they are constantly

Reshaping the very environments that determine them, performing who they are becoming, creating culture and transforming the world. The “products” of this activity are not outcomes, but part of the unity that is “process and product” or “tool and result.”

Holzman (2009, p. 20).

Holzman’s concepts of reshaping, performing and transforming indicate that children are capable citizens who participate in the lives and activities of their communities. They do not wait for adults to organize knowledge, skills and concepts into manageable or simplified stages. Cognition, affect, relationships and imagination are part of this unity as children co-create their cultural identities and capabilities through their interests and inquiries (Hedges, 2022), and extended repertoires of participation. Progression is understood as children participating collectively in more complex social situations for development, using different forms of cultural knowledge, and performing with increasing agency, expertise and control. Children find their own ways of pitching in, and contributing to the development of the activity, with movement and direction building over time, and not just in one event or episode. From this perspective, the established concepts of “active learning” through “hands-on experiences” require further elaboration because the focus has shifted from agency as an individual/developmental trait, to agency being collective, relational and distributed. Acting with agency, and cultural tools, children drive their own and each other’s development in ways that may, over time, align with curriculum goals, but are likely to extend beyond those boundaries to reflect the complexity of play and of children’s life experiences. Socio-cultural theories understand play as a social practice, fundamental to children’s agency and motivation.

Play as social practice

Referring to the canon of knowledge that underpinned ECE from the 19th and early 20th centuries, play is valued as a natural developmental process, the main focus of the child’s activity and the child’s world. The concepts of child-initiated activity, freedom, discovery and exploration, have remained central to the powerful discourse that reifies play as the predominant way in which children learn. However, within global policy flows government investment in pre-school education is framed by discourses such as raising quality, improving children’s outcomes, and addressing social inequalities (Hunkin, 2021). Play has been drawn into socio-political discourses of educational and economic effectiveness, with many regions and countries creating curriculum guidance documents with varying degrees of prescription and description of desired outcomes (Gunn and Nuttall, 2019; Yang and Li, 2019). Within those frameworks, play occupies an ambivalent position (Wood, 2014), especially within the education-economic rationale for government investment. The emphasis in many policy frameworks has shifted toward a technical or utilitarian perspective, where play must pay into curriculum outcomes and goals (Hedges et al., 2018; Wood, 2020; Yang and Li, 2019). There are debates about the relative merits of child-initiated and adult-led play, and recommendations about play-based pedagogy and play-based curriculum can be in tension with children’s peer cultures, choices and interests (Chesworth, 2019). The move from pre-school to compulsory school varies internationally from age 4/5 to age 6/7 years old, with play being phased out in the transition year to ensure that children are “school ready.” The policy focus on “educational play” should not detract from the importance of play for its own sake, regardless of the age at which children make this transition.

Debates about the relative merits of child-initiated and adult-led play foreground key socio-cultural principles about the role and value of play for children’s meanings and purposes, and not necessarily for producing defined learning outcomes. It is worth returning to the concept of “play for its own sake,” because play connects children’s home, family and community life to the distinctive culture of education settings. Being in a pre-school or kindergarten offers new and varied opportunities for play, with different adults, peers, materials, space, tools and resources. Although Vygotsky wrote little about play, his indicative theories have been foundational to further research on understanding play across time, contexts and cultures. Vygotsky (1978) understood play as

a leading activity in early childhood. This does not mean that play is the most important or the predominant activity, rather that play creates zones for proximal development that are child-initiated and child-led. Play integrates social and symbolic complexity, expressed through language and multi-modal communicative practices. Cultural tools and resources may be imbued with pre-determined meanings (a pencil for writing, a buggy for a baby), but meanings can be imaginatively reconfigured in the context of play (a pencil becomes a light saber, a buggy becomes a forklift truck).

For [Vygotsky \(1978\)](#) and subsequent theorists, freedom of choice, imitation, imagination, and activity with imagination, are defining characteristics of play. [Vygotsky \(1978\)](#) identified the powerful role of imitation in play. Imitation is not merely “copying” what children see and experience in their everyday social worlds. Rather imitation is a highly creative process that involves mediation, creative interpretation, and recontextualization, with the addition of imagination and pretense to create and convey meaning. Imitation is informed by diverse sources of knowledge as well as everyday roles and practices in children’s homes, communities and families. Within play, children’s interests, and their cultural and linguistic repertoires become visible, because they can use their environment to establish and experiment with their identities through their language choices ([Fashanu et al., 2020](#)). Cultural tools and resources can be re-mediated and re-contextualized according to the nature of the activity, or the play theme, and children’s purposes or intentions.

Different interpretations of the ZPD can be found in a substantial body of work that focuses on children’s funds of knowledge and interests in play ([Chesworth and Hedges, 2023](#); [Hedges, 2022](#)). Play creates zones for proximal development that are child-led, collective and relational, and draw on the cultural resources of the setting as well as children’s home and community lives. [Chesworth \(2019\)](#) draws on sociological theories to focus on children’s peer cultures, and understands play as a shared social practice that supports the development of intersecting interests, identities, languages and knowledge/ways of knowing. [Hill and Wood \(2019\)](#) report an ethnographic study of children, aged 4–5, building working theories in their play-based activities. The children contributed collectively to creating interests as inquiries, and to co-constructing knowledge. They drew on working theories about human nature, the social world, and the physical and natural world, as well as existential matters of birth, life and death, which derived from their home and family experiences, including popular culture, religious beliefs and everyday practices.

Play remains a complex space for research, theory and practice, with the addition of policy as a fourth dimension. Analyses of early childhood policy frameworks indicate that play has earned its place within the broad recommendations for play-based learning, play-based curriculum and play-based pedagogy ([Hedges et al., 2018](#)). However, the capture of play in policy discourses and curriculum frameworks is a mixed blessing because there are varying interpretations of what counts as play, and what play is expected to produce. Finding a “best fit” between the apparent orderliness of curriculum frameworks and the complexities of play remains problematic ([Ruscoe and Barratt-Pugh, 2021](#); [Wood, 2013](#)), and the urge toward “structured” and “guided” play leans more toward apparent orderliness. With the play/education debates, there are different positions. Free play is seen as relevant for achieving developmental goals, and adult-guided/structured play being more appropriate for achieving academic goals ([Pyle and Danniels, 2017](#)). This bifurcation indicates that biological/maturational theories of play retain power within the field, where development leads learning. At the same time, curriculum frameworks in different countries exert different degrees of pressure on educators, according to the levels of prescription of defined outcomes (for example in England) and description of indicative goals (for example in New Zealand) ([Barblett et al., 2016](#); [Gunn and Nuttall, 2019](#); [Wood and Hedges, 2016](#); [Wood, 2020](#)). Connecting play with curriculum and pedagogical approaches, [Pyle and Danniels \(2017\)](#) propose that “purposeful play” sits on a continuum between developmental goals and academic goals, but this remains a problematic construct depending on whose purposes are privileged—those of the children, or those of the educators. [Fleer \(2015\)](#) focused on the pedagogical roles of educators inside and outside imaginary play situations. The educators in the study acted in five different ways according to the physical positioning or proximity to the play, the levels of intersubjectivity between adults/children, resourcing and supporting the play theme, being engaged with the play, and being inside the play, in imaginative but restricted ways. Fleer’s research exemplifies the range of possible pedagogical decisions and actions that educators take in relation to play, and the challenges of sustaining imaginative play against more instrumental discourses within ECE policy frameworks. For Vygotsky, school instruction and work are “compulsory activity based on rules” (1978, p. 104). This is not to downplay how children engage with the knowledge around which curriculum content is framed, as they are being/becoming mathematicians, geographers, scientists, artists, technologists, readers, writers, designers and players. However, children also draw on sources and funds of knowledge from their own cultural repertoires to inform how they experience and build curriculum ([Chesworth, 2016](#); [Hedges, 2022](#); [Hill and Wood, 2019](#)). Extending these concepts, [Stagg-Peterson and Friedrich \(2022\)](#) elaborate the interrelationship between play and place as “playce” to foreground Indigenous philosophies and ontologies, in which the nature of being/becoming is embodied in concepts of Land, place and space.

The role of early childhood educators is critical to interpreting policies in ways that honor the significance of truly free play in ECE settings, but at the same time ensure that all children can be involved in creatively shaping their own developmental environments. From the perspective of play, curriculum is not understood as hierarchical or linear goals. Rather curriculum design and enactment are dynamic and co-constructive processes, informed by children’s identities, interests, heritages, languages, knowledges and practices. For early childhood educators, the pedagogical implications are complex: understanding what lies beyond the boundaries of curriculum goals and outcomes informs the design of culturally responsive curricula that includes and values children’s diverse home and community knowledge.

In light of the substantial investment in ECE in many regions of the world, it is not surprising that play has been drawn into debates about the different purposes and practices of education. Play occupies a tenuous position in practice and is perhaps most vulnerable to being marginalized in favor of adult-led activities, or guided play, as a means of ensuring children achieve defined goals, and are “ready” to make the transition to compulsory education. Debates about the role and value of play are

enmeshed with wider debates about what and whose knowledges are valued, and how ECE curricula should be designed to reflect dimensions of diversity. Play is thus implicated in the global politics of knowing, learning, teaching, and governing.

Section 3: What are the implications of socio-cultural theories for early childhood education?

This chapter has focused on some of Vygotsky's original ideas, and their subsequent interpretations over time, along with critical perspectives from post-structural theories. The continued working out of socio-cultural theories remains an important endeavor in ECE practice, and in policy frameworks. The two orientations discussed here—development leads learning, and learning leads development—are not mutually exclusive, and can be understood in dialectical relationship. However, an emphasis on one at the expense of the other produces different ways of understanding children's agency, with different implications for creating education spaces, and designing curriculum, pedagogical and assessment practices. Moreover, embedding socio-cultural theories as the foundational knowledge for pedagogy, curriculum and assessment practices remains challenging.

Debates about the nature of pedagogy and curriculum, and the place of play in ECE have intensified in light of trends toward policy frameworks that prescribe or describe desired learning goals and outcomes. Focusing on the Early Years Foundation Stage (EYFS), the statutory framework for children from birth to 5 in England (DfE, 2017), Wood (2020) uses critical discourse analysis to reveal how the prescribed learning outcomes exemplify a global preoccupation with policy technologies to determine linear notions of progress, as a means of shaping children's developmental pathways toward "school readiness." The framing of curriculum and pedagogy is informed by a standardized conceptualization of knowledge in which predetermined learning outcomes are assumed to have universal relevance for all children (Chesworth, 2019), and is aligned with accountability and regulation. Pedagogy and assessment practices are organized to provide comparative data about the extent to which children have acquired, and can demonstrate, developmental goals as learning outcomes. The EYFS exemplifies how selected child development theories remain influential in the field, and have been interpreted to sustain a development leads learning orientation. In contrast, the ECE policy frameworks in Australia (the Early Years Learning Framework) and New Zealand (Te Whāriki) are informed explicitly by contemporary interpretations of socio-cultural theories, as well as critical post-structural perspectives (Gunn and Nuttall, 2019). However, there remain challenges for initial and continuing professional development programs in engaging teachers with more complex conceptualizations of children's learning over time. Chesworth and Hedges (2023) identify theoretical and methodological heterogeneity in ECE, incorporating developmental psychology, sociocultural theory, new materialism, and post-humanism. This heterogeneity is informing the urgency of undoing normalization (Vintimilla and Pacini-Ketchabaw, 2020) by challenging normative child development theories, their ethnocentricity (Rogoff, 2003), and their various instantiations in ECE policy frameworks (Wood and Hedges, 2016; Hedges et al., 2018). In combination with contemporary theories, the continuing endeavor to understand changing socio-cultural/cultural-historical contexts for learning and development is informed by critical perspectives. Different interpretations of socio-cultural theories continue to emerge, in ongoing efforts to address new social challenges that play out at local and global levels.

Vygotsky has been described as a "revolutionary scientist" because he was concerned with profound and progressive social change (Holzman, 2017). A century later, it seems that we need to sustain a revolutionary approach to understand children's learning in the context of the profound and progressive changes of the 21st century. Global movements which foreground ethical commitments to children's rights, decolonization, and postcolonial practices highlight the structural inequalities that exist for particular communities. Socio-cultural theories have been reinterpreted to foreground the significance of knowledges and practices within Indigenous communities, including cultural identity and sense of belonging, and how these can inform the contemporary focus on the environment, sustainability and climate change (Stagg Peterson and Friedrich, 2022). Post-developmental theories draw critical attention to the discursive effects of "normal" or "typical" patterns of development (Hatch, 2010, 2012; Vintimilla and Pacini-Ketchabaw, 2020) to address concerns with diversities, equity and inclusion, and generate new understandings of identity and culture. A growing field of critical policy analysis foregrounds concerns with power, and power relationships in governance and policy formulation, in the wider contexts of global policy flows (Kay, 2022; Hunkin, 2021; Wood, 2020). New materialism and post-human theories challenge the primacy of the human in theories of development, and draw attention to relationships between humans and non-humans, place/land, space, materials, tools, and the natural world (Pacini-Ketchabaw and Taylor, 2015; Stagg Peterson and Friedrich, 2022).

Contemporary interpretations of socio-cultural theories remain integral to these challenges. As Rogoff et al. (2018) have argued more attention is needed to the cultural paradigms of children's lived experiences, including how they learn to navigate across, and participate in the distinct cultural settings of their everyday lives. In light of these complexities, a continuing project for all involved in ECE is to engage critically across the intersections of theory-policy-practice to articulate the purposes and practices of education. This is an important point because debates no longer center mainly on the theory-practice relationship in ECE. Rather debates center on policy, theory and practice, ethics and politics, and on critical engagement with the selected research and evidence that underpins policy (Wood, 2020). Research within the learning sciences continues to be relevant to ECE (Goswami, 2015), but it is important to remain critically aware of what methods are used, what forms of knowledge are produced in different disciplinary orientations, and how findings are used selectively in the contexts of policy and practice. Ellefson et al. (2019) draw critical attention to the structural and cultural differences between educational and psychological research, and the complexity of using research findings to inform policy making and decisions. They argue that

Findings can be much more influential if they account for this complexity from its earliest conception through shared agenda setting and the cocreation of more appropriate research designs that benefit both education and psychology (2019, p. 254).

For post-structural researchers, methods and methodology are part of the challenge, specifically the notion of research as the application of specific methods or tools, in a linear process, to produce results that inform policy ideologies, often in piecemeal or selective ways. Hunkin (2021) argues for a new advocacy focus on questioning edu-policies and politics on ontological and epistemological grounds, particularly the different conditions of workforce and governance that mark ECE as distinct from compulsory schooling. Hunkin's work foregrounds the necessity for political engagement with policy discourses, and their promotion of particular truths, including early learning inputs and outcomes (p. 203).

Different theoretical perspectives have brought about methodological innovations, which were not used in Vygotsky's original research, as well as ontological and epistemological shifts in understanding learning and development. In particular, an ethical focus on children as participants in research respects them as informed interpreters of their own lives and experiences (Robson and Flannery Quinn, 2015). What we understand as social, cultural, and material has expanded with rapid shifts in technologies, their uptake by young children, the convergence between physical and digital play and everyday activities, and the global influence of popular culture. Post-colonial attention to inclusion, equity and diversities in families and communities challenges ethnocentric assumptions in policy, theory and practice. Ethical-political concerns regarding the decolonization of theory and practice locate ECE within the politics of knowing, learning and teaching (Gunn and Nuttall, 2019) and draw attention to new modes of governing, and their impacts, in the context of global/local reform movements (Hunkin, 2021; Lee, 2021).

Socio-cultural/cultural-historical theories continue to be relevant for understanding human development in contemporary contexts, where rapid changes and new social challenges are provoking new relationships between human beings and society, between human- and non-human beings, and between humans and the natural and made environments. These issues imply that the education and care of young children needs to acknowledge their agency and capacities for engaging in and with their social worlds, specifically matters that interest and concern them. Socio-cultural theories remain relevant for articulating and critiquing the diverse policies, purposes and practices of early childhood education. However, a key challenge for the field is to further explore the theoretical heterogeneity identified in this chapter, and the implications for informing ECE in the context of social and technological change, and global influences.

Key developments in adolescence

Adolescence is a pivotal developmental period. During the adolescent years, youth are developing rapidly across a wide range of domains. They are experiencing changes in the ways that they think, in their beliefs about who they are and whom they might become, and in their relationships with peers and adults. The numerous changes that occur during this time period greatly impact adolescent learning.

We focus in this chapter in particular on developmental trajectories and milestones that affect academic learning during adolescence. When educators, parents, and policymakers are aware of the complexity and inter-relatedness of development across a variety of domains during adolescence, they are better able to provide developmentally appropriate instructional practices to support adolescents' success in their academic pursuits. This is important, because research clearly indicates that when instructional practices and contexts are aligned with adolescents' developmental needs, adolescents are likely to achieve at high levels and maintain optimal motivation (Eccles and Roeser, 2009).

We discuss four domains of development: cognitive, social/moral, identity, and motivation. Whereas development within each of these domains can be discussed in isolation, it is essential for educators and policymakers to acknowledge that adolescent development occurs across these four domains simultaneously; thus changes in one domain (e.g., cognitive development) are not independent of changes in another domain (e.g., moral development). These changes, though largely predictable and generalizable to adolescents across different cultures, may naturally occur at stages unique to each individual as he or she progresses from childhood to adolescence and into adulthood.

We first briefly review the major developmental milestones associated with each of these domains. We then provide a more holistic overview of the interrelations of development across these domains.

Cognitive development and adolescent learning

Of the fundamental changes that occur during adolescence, cognitive changes have far-reaching implications for learning and the processes adolescents can use to enhance their learning. Generally, there is agreement that adolescents think differently than children. However, the processes that underlie the cognitive differences in learning between children and adolescents are less universally accepted. Various periods of growth experienced by an individual may be influenced by both biological (i.e., genetic) and environmental (i.e., physical and social/environmental) factors. The debate of heredity versus environmental influences on cognitive development was once seen as an “either-or” debate (Bradley et al., 1989; Greenfield and Bruner, 1966; Newman et al., 1937). However, scholars today readily agree that heredity and environment are intermingled in such a way that one’s influence cannot be separated from the other (e.g., Petrill et al., 2004; Plomin and Asbury, 2005; Tucker-Drob et al., 2013).

Cognitive development prior to and during adolescence is influenced by a variety of factors (e.g., genetics, nutrition, physical and social environments), and development is reflected by ongoing physiological changes in the brain (Bronfenbrenner, 1992). For this chapter, we focus on three psychological perspectives that describe cognitive development during adolescence, rather than focusing on neurological development in the brain. Specifically, we focus on Piaget’s theory, Vygotsky’s theory, and metacognitive or information processing perspectives of learning and development.

Piagetian perspective of adolescent learning and development

Jean Piaget’s theory of cognitive development (Piaget, 1929, 1952, 1964) has been highly influential in understanding the cognitive changes that occur throughout childhood and adolescence. In his observation of children and adolescents, Piaget noticed various changes in logical thinking patterns. He asserted that these cognitive shifts are both sequential and distinct, and that the type of thinking employed by children and adolescents is different. Known as a constructivist view of learning and development, Piaget noted that children are active, motivated learners who construct knowledge rather than absorb it. Children learn through assimilation (modifying new information to fit what one already knows) and accommodation (restructuring what one already knows to integrate new information). They also interact with their surroundings; these interactions may lead to disequilibrium in thought, ultimately promoting progress toward more complex thought.

According to Piaget (1964), the process of cognitive development proceeds through four separate stages, hierarchical in nature, and each characterized by a particular type of thinking: *sensorimotor* (birth through age 2), *preoperational* (generally ages 2–7), *concrete operational* (generally ages 7–11), and *formal operational* (approximately age 11 onward). It should be noted that individuals transitioning from one stage to the next may exhibit characteristics of two adjoining stages simultaneously. Also, as children progress from one stage to the next, they do not lose the abilities gained in prior stages while gaining newer, more advanced thinking abilities. Furthermore, Piaget’s stages of cognitive development describe how individuals can think, rather than how they actually, or always, do think. We very briefly describe the milestones associated with each of these stages.

Sensorimotor stage

Early in life, one’s actions and thoughts (known as schemas) are based mostly on exploration of an infant’s surroundings. Infants and toddlers use their senses and engage in actions (e.g., crawling and walking) that allow them to experiment through looking, hearing, touching, mouthing, and grasping. Very young children cannot think about things that are not directly in front of them, until object permanence and symbolic thought emerge.

Preoperational stage

During this stage, symbolic thinking abilities increase dramatically, allowing for greater ability to represent and refer to objects outside of immediate experience. This results in a great expansion of vocabulary and language structure, increased pretend play, and intuitive thought.

Concrete operations stage

Throughout this stage, children begin to think logically and understand analogies, but only concretely (i.e., pertaining to real-life situations). Abilities acquired during this stage include distinction between thoughts of self and others, categorization of objects in simultaneous categories, and conservation.

Formal operations stage

Young adolescents begin to apply logical thinking and reasoning processes to both abstract and concrete ideas and objects. Adolescents develop the ability to engage in logical and deductive reasoning, to consider hypotheticals, and to think about abstract topics. Moreover, metacognitive abilities develop further, thus enabling adolescents to think about their own cognitive and self-regulatory processes.

Limitations of the Piagetian perspective

Piaget's idea that children construct their own knowledge is widely accepted. However, Piaget's stages of development have limitations. For example, children have been found to engage in formal operations at younger ages (e.g., Kuhn, 2008; Siegler, 1998). Moreover, aspects of cognition may develop more sporadically, rather than through highly predictable stages (Keating, 2004, 2012; Kramer, 1983; Kuhn, 2008). In addition, the concepts of assimilation and accommodation, which are critical to Piaget's theory, remain quite vague, and interactions with the physical environment are not necessarily limited to direct sensory experiences (Bebko et al., 1992; Brainerd, 2003).

Vygotskian perspective of adolescent learning and development

Rather than children independently constructing their own knowledge, Lev Vygotsky believed that adults systematically influence and foster children's cognitive development. This is known as a sociocultural theory of cognitive development (Vygotsky, 1978, 1987). Vygotsky's sociocultural theory of development, first introduced nearly 90 years ago, framed cognitive development around the central notion that children completing tasks with adult assistance promotes cognitive development.

According to Vygotsky (1987), learning is a social activity. Learning occurs formally and informally through interactions with more experienced others. Cognitive tools (general learning techniques or processes) passed on to children and adolescents by more experienced peers, teachers, parents, or other influential adults, enhance cognitive abilities and eventually are internalized as individuals engage in various activities. Internalization of these cognitive tools leads children and adolescents to gradually learn to independently direct their own mental activities, rather than needing the support and guidance of others.

The zone of proximal development (ZPD), fundamental to Vygotsky's theory, is represented by the range of tasks or activities which a child or adolescent cannot yet perform independently but can perform with the guidance and help of a more experienced other (Vygotsky, 1978, 1987). A child can typically perform certain tasks successfully without the assistance of another; however, learning is typically not stimulated by independent completion of tasks one can already perform. In Vygotsky's view, learning occurs within the ZPD. The ZPD is limited however, as there are tasks a child cannot perform, even with aid and support of another. Naturally, an individual's ZPD will change over time as various tasks are mastered and more complex, difficult tasks are encountered. The ZPD is representative of one's actual (independent) development level and their level of potential development (Vygotsky, 1978, 1987).

Metacognitive and information processing perspectives

Thinking about thinking—or metacognition, is representative of an individual's own knowledge about his or her own cognitive processes. The characterization of thinking abilities that change from childhood into adolescence is encompassed by the information-processing perspective. Between childhood and adolescence, cognitive development is evident in youth's attention, memory, speed, organization, and metacognition (Demetriou et al., 2002; Keating, 2004). Improvements in each of these areas occur as individuals transition from childhood into adolescence, evidenced by the emergence of advanced cognitive abilities, such as abstract thought and hypothetical thinking (Keating, 2004).

The ability to attend to selective stimuli improves over time. Both selective (focus on one stimulus while turning out other stimuli) and divided (focus on two stimuli simultaneously) attention improve as children mature. Thus, adolescents are better able to focus on one stimulus while tuning out other stimuli, as well as pay attention to two or more stimuli simultaneously (Higgins and Turnure, 1984; Kuhn, 2009). Memory encompasses both working memory (short-term) and long-term memory. Adolescents are better able to temporarily store information in short-term memory than are younger children. Moreover, adolescents can more easily recall information stored in long-term memory (Kuhn, 2008). Adolescents are also better able to quickly and efficiently process and solve problems than are younger children (Kail and Ferrer, 2007). Additionally, adolescents are more adept at organization than are younger children (i.e., they are more planful; Siegler, 1988). Finally, metacognition refers to one's knowledge about their own cognitive processes. Adolescents can more easily think about their own thoughts, and experience greater self-consciousness, self-reflection, and self-awareness. Improvements in metacognition lead to an increase in the ability to monitor and reflect upon learning processes and strategies (Kuhn, 2009).

Summary

The three perspectives that we have reviewed each contribute to our understanding of cognitive development. Each perspective offers unique insights that are relevant to adolescent learning. For example, the Piagetian perspective reminds us that adolescents are more able than are younger children to understand and engage with abstract, complex ideas (e.g., debating about the causes of poverty). The Vygotskian perspective reminds us that many topics are best learned when adolescents can partner with more experienced peers or adults. Thus, an adolescent who is struggling with a complex trigonometry problem might be better able to understand and learn the strategies necessary to solve the problem when working with a partner who has a deeper understanding of trigonometry. The information processing perspective reminds us that there are multiple cognitive processes that develop throughout childhood and adolescence. For example, educators often can teach organizational strategies to adolescents, and expect that those adolescents will be able to learn and eventually apply those strategies in novel contexts.

Social/moral development

During childhood, the critical tasks of social/moral development and learning include the acquisition of an understanding of various norms and expectations that apply in different social/moral contexts, as well as an understanding of the beliefs and feelings of others (i.e., theory of mind). As children transition toward adolescence, multiple internal and external factors impact ongoing social/moral development and learning. For example, with enhanced cognitive ability (e.g., abstract and hypothetical thinking), adolescents are able to understand and interpret social/moral issues they encounter. Concomitantly, the social situations and relationships that adolescents experience expand and become increasingly complex and multifaceted, requiring them to think critically about the complex and sometimes conflicting issues which arise (e.g., equity, justice). Adolescents are more able than younger children to make sense of, evaluate, and reconcile various perspectives, in order to thoughtfully participate in society.

We briefly review several central issues in the study of adolescent social and moral development. First, we discuss several theoretical approaches regarding the development of individual social/moral reasoning during adolescence. Second, we discuss the roles that adolescent social relationships and experiences play in social/moral development and learning.

Theoretical perspectives on social/moral development

Current research and theories on social/moral development can be traced back to the work of [Piaget \(1932\)](#) and [Kohlberg \(1973\)](#), which suggested that humans use multiple social perspectives to make sense of social events. Piaget used the term “social-arbitrary knowledge” to describe the type of knowledge needed in the understanding of humans and social interactions. Social-arbitrary knowledge consists of the manners, rules, and signs accepted and agreed upon by members of a society. One can learn this kind of knowledge through various types of interaction with others, such as communication and instruction. [Kohlberg \(1964\)](#) viewed moral competence as “the capacity to make decisions and judgments, which are moral (based on internal principles) and to act in accordance with such judgment” (p. 425). According to Kohlberg, moral competence develops with age as individuals become increasingly able to distinguish morality from social conventions, and to mentally coordinate these different perspectives. [Kohlberg \(1973\)](#) asserted that most adolescents are capable of making social/moral decisions based on external rewards or punishments and self-interest, and that they begin to recognize the value of maintaining, supporting, and justifying interpersonal and societal rules and expectations (c.f., conventional level of moral development). However, Kohlberg also posited that in general, adolescents are not yet capable of making autonomous and conscious decisions based on abstract and ethical principles that are consistent with universal principles of justice and rights.

Extending Piaget and Kohlberg’s framework on social/moral development, more recent approaches have focused on how children and adolescents coordinate and apply different social and moral beliefs to different social/moral situations (e.g., peer interactions, social interactions involving different cultures). Social domain theory ([Turiel, 1983](#)) posits children’s (even young children’s) ability to construct three conceptually distinct domains of social understanding—moral, societal, and psychological—through social interactions and experiences. The moral domain pertains to understanding issues like justice, fairness, and rights. The societal domain involves the understanding of authority, tradition, norms, and expectations within social systems. The psychological domain includes matters that primarily affect the self, such as privacy, personal choice, and preferences. Additional domains, such as pragmatic considerations (i.e., understanding of practical issues such as convenience) and prudence (i.e., understanding issues related to one’s own safety, comfort, and health) were later identified and have been examined in more recent research ([Smetana and Turiel, 2003](#); [Tisak, 1993](#)). Developmental research based on the social domain perspective (e.g., [Nucci and Turiel, 2009](#)) suggests that in ambiguous social/moral situations, early adolescents tend to emphasize personal rights, whereas older adolescents exhibit a more sophisticated ability to consider and coordinate diverse aspects of social/moral situations (e.g., government has the right to constrain individuals’ rights for a larger public good). Thus during adolescence, the ability to understand social/moral situations extends beyond a focus on familiar and concrete social/moral events (e.g., physical harm); indeed, adolescents become more able to appreciate the complexity of the ambiguity that is inherent in social/moral discussions.

The roles of adolescent social relationships and experiences

There is a general consensus that interpersonal experiences, particularly with parents and peers, play critical roles in social/moral development ([Dodge et al., 1990](#); [Eisenberg et al., 2015](#)). Parents’ use of inductive discipline methods, including the use of explanations, rationales, and reasoning, as well as having an authoritative style of parenting, help facilitate the development of adolescents’ advanced moral reasoning and prosocial behavior. These parental practices provide information about the nature of social/moral transgressions, and encourage adolescents to feel empathy toward others, and reflect on their actions, contributing to prosocial development. One of the key processes that occurs during adolescence is the renegotiation of parent-child relationships. Parent-adolescent relationships that acknowledge adolescent needs for independence and autonomy and that enable open communication—rather than trying to control adolescent behavior and feeling—have been associated with positive adolescent outcomes, such as better self-control, better academic performance, and fewer school behavior problems (e.g., [Barber, 1996](#); [Lam and Ducreux, 2013](#)). On the other hand, adolescents living with hostile and rejecting parents are more likely to display hostile attribution bias, aggressive behavior, and fewer positive social skills, all of which are detrimental to successful interactions with peers ([Dodge et al., 1990](#); [Repetti et al., 2002](#)).

Younger children's notions of friends and friendship often refer to acquaintances and focus on simple, shared activities. Adolescents, however, begin to form more intimate relationships with their peers. Adolescents within peer groups tend to be similar to one another in a variety of attributes such as attitudes, values, and behavior. On one hand, adolescents select peers who are similar to them; on the other hand, friends who spend time together shape each others' attitudes, values, and behaviors. These two processes both play roles at different points in the formation and maintenance processes of peer relationships (Kandel, 1978).

Peer relationships can serve both positive and negative social/moral functions during adolescence. Positive peer relationships often are egalitarian and characterized by intimacy, self-disclosure, and mutual responsiveness. Positive peer relationships can provide opportunities for role taking, negotiation, and cooperation, as well as developing a more empathetic psychological understanding of peers (Kohlberg, 1964). However, peer relationships also can be problematic. For example, perceived pressure from peers can lead adolescents to make risky decisions or engage in problematic behaviors (e.g., alcohol and substance use, criminal activity). The perceived pressure to conform to peers generally rises in early adolescence, peaks at about age 14, and then declines through age 18 and beyond. Moreover, being rejected by one's peers may lead to subsequent unfavorable outcomes, such as biases in social information processing, which may result in aggressive responses and behaviors (Dodge et al., 2003).

Expanding social networks

Adolescents are exposed to larger social networks than are younger children, and these larger networks increasingly affect social/moral development. Adolescents' micro-level relationships (e.g., relationships with family members) evolve within these larger social networks (e.g., culture, society). The norms and expectations of other members of these larger communities (including adult role models) are more likely to be internalized by adolescents than by younger children. Research suggests that neighborhood contexts influence adolescents' attitudes toward risky behavior and deviance (e.g., violence, teenage sex, pregnancy, and drug use; Bingenheimer et al., 2005; Warner et al., 2011; Warner, 2016). In addition, adolescents today are among the most avid users of digital technology and social media. In 2018, 45% of American teenagers (13–17 years) were reportedly connected to the Internet "almost constantly," a nearly twofold increase of adolescents' near-constant online presence reported in 2014–15 (Anderson and Jiang, 2018). The uptake of social media can provide more opportunities for adolescents to communicate with others, establish relationships including romantic relationships, and civic engagement.

Summary

Both children and adolescents' beliefs, behaviors, and attitudes within the social and moral domains change over time. As youth develop more advanced cognitive capabilities (e.g., the ability to understand abstract concepts), they are better equipped to learn from peers and adults in their expanding social networks. Educators can support adolescents' social and cognitive development by providing opportunities for them to engage with peers and adults while pursuing prosocial goals. For example, educators might encourage adolescents to engage in community service initiatives; indeed, research suggests that engagement in community service supports positive development of adolescents' competence and attitudes in the academic, social, and civic domains (e.g., social responsibility, appreciation of diversity, social responsibility; Van Goethem et al., 2014). Lastly, the development of wireless communications technology has enabled adolescents to connect with others without geographical constraints, and form and maintain social relationships virtually, drastically changing the way they socialize and redefining the realm of social/moral development.

Identity development and adolescent learning

Identity can be understood as an individual's perception and understanding of themselves and how they believe they are perceived by others. Many aspects of identity develop during adolescence. In adolescence, youth define who they are and see changes in all aspects of identity. They may be trying to answer the questions: "Who am I? And who do I want to be?" They are attempting to define their biological, social, and psychological identities. Adolescents may feel pressured to conform or assimilate to a societal norm among peers and with adult influences. If they differ from this majority group identity, they may struggle in school and face adversity.

Identity development may be the most extended developing aspect of adolescence beyond cognitive and physiological development. Identity development can begin in late childhood, around age ten, and continue into emerging adulthood around age 23 or 24. However, even after adolescence, identity can continue to change and develop well into adulthood (Arnett, 2000).

Exploring and changing identities

Erik Erikson proposed that the only way to form a strong identity is through exploration and experimentation with various identities (Erikson, 1968, 1995). James Marcia expanded on these ideas, arguing that adolescents may take various pathways in developing their sense of self (Marcia, 1980). Marcia put forth a four-stage model of identity development. These stages are categorized by whether the individual is still in exploration and whether the individual feels a commitment to this identity. The four stages are (1) identity achievement, (2) identity moratorium, (3) identity foreclosure, and (4) identity diffusion.

In Marcia's model, *identity achievement* is the most advanced stage of identity development. In identity achievement, the individual has gone through exploration and has now committed to one identity path. Identity moratorium and foreclosure are

both intermediate stages. In *identity moratorium*, the individual is exploring many identities but has not committed to any. In *identity foreclosure*, the individual has committed to an identity, but did not go through exploration. Finally, *identity diffusion* is the least advanced stage. In identity diffusion, an individual is neither exploring nor committing to any paths.

Marcia's model allows for explanations of different ways adolescents develop identities. However, building on this framework, we must remember that identity is fluid and not unidimensional. As adolescents age, they become more aware of how different groups of people are similar or different from themselves, and how they may act differently across different contexts with different groups of people. Adolescents' identities are dynamic and ever-changing (Arnett, 2000).

Possible selves and self-concept

The fluidity of identity adds to how adolescents view themselves, and their perceptions of their future identities will shape their identity development. This idea of *possible selves* allows adolescents to consider who they are now and who they may be in the future (Markus and Nurius, 1986). These possible selves include their hoped-for self (i.e., the self they most hope will describe them in the future), their feared-self (i.e., the self they most fear will describe them in the future), and their actual self (i.e., the self they feel they are actually most likely to be).

These possible selves contribute to adolescents' identities and how they view themselves. Adolescents' *self-concept* (i.e., how they feel about themselves in different contexts) is influenced by who they see themselves as now and who they see themselves as in the future. In turn, adolescents' self-concept will influence their *self-efficacy* (i.e., their confidence in their own abilities with specific tasks), their *self-esteem* (i.e., their global feelings about themselves), and their *self-worth* (i.e., their global feelings about their own value; Baumeister, 2013; Bong and Clark, 1999).

Gender identity

Before discussing gender identity, it is important to understand the difference between gender and sex. Sex is typically assigned as male and female; it is determined by chromosomes and is assigned at birth (Helgeson, 2020). Gender is an individual's assessment of themselves, and it may or may not align with their sex. Gender identity often becomes particularly salient during adolescence (Guz et al., 2021). Adolescents' gender identity refers to how they view themselves and their gender; it is how they define their gender for themselves. Adolescents' gender roles refer to the expectations they hold for their gender and the societal roles they expect to fill. Adolescents' social interactions and influences in their everyday experiences will shape how they form and view their identities.

Individuals begin to understand gender during childhood but further define their own gender identity beginning during adolescence (Ferrer-Wreder et al., 2020). Bussey (2011) put forth a model of gender identity in which adolescents' gender identity is co-constructed through individual factors (i.e., personal understanding of gender, sex, and other processes such as self-efficacy), behavioral factors (i.e., individuals' performance of gender in day-to-day life and different contexts), and environmental factors (i.e., how others see an individual's gender socially, culturally, and historically).

All the factors suggested by Bussey (2011) are brought to the forefront in educational environments where adolescents interact with peers and teachers. Adolescents may feel pressure to perform to societal norms of "masculinity" or "femininity." However, adolescents may become social outcasts if they counter societal norms. Indeed, gender nonconforming youth face high levels of distress, mental health crisis, and bullying (Hatchel et al., 2021). In looking specifically at STEM fields, women and girls are less likely to study STEM subjects in school and avoid fields dominated by men (Dasgupta and Stout, 2014).

Racial and ethnic identity

Race and ethnicity are complex identities. In early adolescence, children may not have acquired the developmental capability to think about their racial or ethnic identities in complex ways. They may know about their race from their family, and they may even know their ethnicity. However, distinguishing between the two and developing their sense of identity is more likely to happen as they age and become more able to engage with complexity in later adolescence. This is especially true for adolescents in homogeneous environments where they do not encounter many people with races/ethnicities different from their own.

Racial identity is a more biological identity incorporating the physical characteristics of a group. *Ethnic identity* refers to the cultural, historical, and social identities of a group. Thus, an individual may be Asian (racial identity) and Japanese (ethnic identity). Applying Marcia's (1980) stages to racial and ethnic identity, an adolescent may explore the history, beliefs, and traditions of their ethnic group; then, commitment refers to how closely they feel their racial or ethnic group is to who they are.

Adolescents with a more positive ethnic identity who feel more closely tied to their ethnicity and culture often are better able to psychologically adjust in school (Umaña-Taylor et al., 2014). As adolescents begin to understand their race and ethnicity more, they will also begin to understand the prejudices and stereotypes held about their race. Black and Latinx students may not see the same benefits from a positive ethnic identity as their White counterparts due to stereotype threat. *Stereotype threat* is a psychological threat in which a student worries about acting in such a way that confirms a stereotype about a certain identity (e.g., the stereotype that Black students do not perform as well in school or that women do not do as well in STEM fields), which in turn often results in the students fulfilling this stereotype (e.g., scoring lower on tests or devaluing education/certain fields as a whole; Spencer et al., 2016). Of course, this is not the only factor at play that may negatively impact adolescents in school as they struggle with identity

development. Overall, adolescents who have not yet committed to their identity, or who are in identity crisis, will struggle more with academics (Jensen, 2010). Adolescents who feel more secure in their identities are better able to foster adaptive academic habits and positive academic self-concepts.

Summary

Adolescents' conceptions of who they are, and whom they might become in the future, are likely to change during adolescence. As students' self-perceptions change, their interests in various school subjects and the amount of time that they are willing to devote to academic pursuits also may change. Moreover, adolescent identity develops across a range of domains, including their present identities with their peers, the possible future identities that they are considering (e.g., in terms of a profession), and their identities with regard to personal characteristics (e.g., gender, racial, and ethnic identities). Educators who work with adolescents and are attuned to changes in adolescents' self-perceptions can support adolescent learning by allowing and gently encouraging adolescents to explore diverse identities.

Academic motivation development

Adolescence is often associated with a sharp decline in students' motivation. The media, in particular, often portrays adolescents as being bored and disenchanted with school. Research does in fact demonstrate that motivational beliefs change during adolescence; however, these shifts in motivation are not by any means universally detrimental (Wigfield and Wagner, 2005). Adolescents' motivational beliefs are largely determined by the social contexts in which they interact (e.g., Yeager et al., 2017).

In reviewing the research on adolescent motivation, it is important to distinguish between different types of motivational beliefs. In the present chapter, we focus on two specific frameworks that have been examined in longitudinal studies including adolescents. The first framework for examining academic motivation is referred to as Expectancy-Value Theory (and more recently as Situated Expectancy Value Theory [SEVT]; Eccles and Wigfield, 2020; Wigfield and Eccles, 2000). This theory posits that there are two overarching motivational beliefs: students' expectancies for success, and students' valuing of academic content.

Expectancies and values

Expectancy beliefs refer to students' beliefs about whether or not they can be successful in a given domain (e.g., math) or at a specific task (e.g., playing tennis). Students' valuing of academic tasks encompasses four related beliefs. These include (a) attainment value (i.e., the perceived importance of the subject, particularly as it pertains to the student's identity), (b) intrinsic value (i.e., how much the student likes/enjoys the subject), (c) utility value (i.e., the perceived usefulness of the subject area, particularly as it pertains to future goals), and (d) cost (i.e., considerations of what the student might have to give up doing in order to be engaged with the task/subject; Rosenzweig et al., 2019).

Numerous longitudinal studies have examined the ways that students' expectancies and values change during adolescence (see Wigfield et al., 2015, for a review). When children are in the early grades in school, they tend to have high expectancies – they often believe that they can accomplish whatever they set out to do, and that they can learn how to become good at just about anything. But as students move into higher grades, they begin to doubt their abilities in some areas. During early adolescence in particular, students' expectancy beliefs may decline in one or more areas. For example, a third grader might feel very confident at both reading and math, but by the time that third grader reaches the seventh grade, they might still feel confident as a reader, but less so as a mathematician.

Simultaneously, students' valuing of various subject areas also often declines as young children move into adolescence (Jacobs et al., 2002). A young child who deeply enjoyed doing science experiments as a second grader may not find science interesting anymore when that same child is in the ninth grade. Moreover, students' expectancies for success and valuing of academic content are positively related: students who maintain positive beliefs about their competencies in a domain (e.g., reading) are more likely to continue to value that domain, compared to students who do not maintain confidence in their abilities to succeed (Eccles and Wigfield, 2020).

Achievement goal theory

Achievement goal theory (AGT) focuses on the goals that students have when they engage with academic tasks. Although adolescents have many different goals, AGT focuses on two types of goals, each of which can be further dichotomized into an approach-type goal and an avoidance-type goal (Elliot and Harackiewicz, 1996). A mastery goal is the goal of deeply learning about a particular subject or task (Urdan and Kaplan, 2020). Students who hold mastery goals want to “master” the content. They are willing to take the necessary time to understand the topic in depth, they exert a great deal of effort, and they often see mistakes or misconceptions as opportunities to learn, rather than as embarrassing representations of their lack of skill or knowledge. Mastery goals are often dichotomized as mastery approach goals (i.e., the goal is to gain mastery of a particular subject or task), and mastery avoid goals (i.e., the goal is to avoid misunderstanding a topic/subject).

A performance goal is a goal that is focused on a student's perceived ability at completing a task or learning in a particular subject domain (Urdu and Kaplan, 2020). Students who hold performance goals are concerned with how their capabilities to engage with a task compared to other students. A student who is focused on demonstrating their ability in outperforming others holds performance-approach goals, whereas a student who is focused on avoiding appearing "dumb" or unable to complete a task holds performance-avoid goals.

Longitudinal studies also have examined the ways that achievement goals change during adolescence (e.g., Anderman and Midgley, 1997). Similar to expectancies and values, students' achievement goals often shift as students move into higher grades. Students often become more focused on performance (i.e., how they compare to others) and less focused on mastery (i.e., taking the time to learn deeply about a topic) as they progress into higher grades. In particular, adolescents tend to become more focused on performance (as well as on extrinsic outcomes) and less focused on mastery as they transition from elementary school into middle school (Anderman and Maehr, 1994).

Why do motivational beliefs change during adolescence?

Whereas stereotypes in the media often characterize adolescents as being lazy and often attribute declines in motivation to physiological development, current scholarship suggests that negative shifts in motivational beliefs are strongly attributable to changes in social contexts. Studies conducted both using SEVT and AGT indicate that the academic climates in many elementary school classrooms are focused on mastery, exploration, and individual progress, whereas the climates in many (but certainly not all) middle schools and high schools become more focused on grades, ability difference, and social comparison (e.g., Anderman and Midgley, 2004).

For example, when students transition from elementary school into middle school, they often encounter more grouping by ability than they experienced in elementary school. When students are placed into a seemingly low-achieving class in a given subject area (e.g., science), those students may begin to doubt their abilities to succeed in those subject domains, and consequently may come to value those subjects less. Relatedly, negative shifts in ability perceptions and values can potentially affect long-term career considerations (Anderman and Patrick, 2012). Indeed, a child who was considering a career in science might have a change of heart when that child is suddenly "told" by their middle teachers that they are not as good at science as many of their peers (because they were placed into a lower-achieving classroom). Studies from an AGT perspective also mirror these observations, with students who have recently transitioned into middle schools often reporting increases in performance goals and decreases in mastery goals (e.g., Anderman and Midgley, 1997).

Summary

Students' motivation toward academic pursuits changes during adolescence. Whereas the quality of motivation does decline for some youth, downward turns in motivation are not inevitable. Adolescent motivation is not a unidimensional construct. Adolescent motivation can be conceptualized in a variety of ways. Indeed, motivation during adolescence is a function of students' expectancies for success, their valuing of various academic (and non-academic) subjects, and their goals while engaged with academic tasks. Adolescent motivation is particularly sensitive to contextual influences. When schools emphasize grades and ability differences, adolescents may focus on their grades and performance, more so than on the intrinsic value of what they are learning.

Discussion

Adolescence is a period of dramatic change. Whereas the physical growth and maturation associated with adolescence is prominent, equally important are the changes that are occurring in psychological domains. Adolescents differ from younger children with regard to their cognitive capabilities, their comprehension and understanding of social and moral issues, their beliefs about who they are and who they hope to become, and their motivation toward academic work and school success (Anderman, 2012).

Adolescence is a broad period, often inclusive of a wide range of ages (e.g., sometimes youth as young as 10 or 11 are considered adolescents, and at times young adults in their early twenties are still referred to as adolescents). It is imperative for educators to carefully and critically consider the ongoing effects of all of these developmental shifts on learning (Eunice Kennedy Shriver National Institute of Child Health and Human Development NIH DHHS, 2007). Nevertheless, development in all of the psychological domains reviewed in this chapter transpires via varying trajectories. It is particularly important for teachers of adolescents to understand and acknowledge that their students will be at different stages of development both within and across these domains.

To illustrate, consider a language arts teacher who instructs students who are 14–15 years old. In the United States, these students would probably be in the 9th grade. Let us suppose that the class is reading a short story, and that one of the central characters in the story works at a fast food establishment, and is caught stealing some food at the end of their shift. The language arts teacher might decide to ask the class to discuss the incident, and to consider whether the character was justified in stealing the food. The teacher would probably hope that the students would consider other circumstances surrounding the incident that had been described in the story (e.g., peer pressure; food insecurity; the student's ability to understand how their actions might impact others; etc.).

A productive discussion around this topic would draw upon many of the topics addressed in this chapter. Students might respond differently to the scenario based on their own abilities to understand the complexities of the situation (i.e., cognitive domain), to consider the reasons as to why the food was stolen (i.e., social/moral domain), to empathize with the character and consider how this action might affect one's future goals (i.e., identity domain), and to consider the student's motives that precipitated the action (i.e., motivation domain). Nevertheless, adolescents who are 14–15 years old inevitably will be at different places with regard to their development in these four domains. Students are likely to analyze the character's actions (i.e., stealing) based on their own developmental levels. Consequently, some students are likely to disagree with each other with regard to their interpretations of the incident. Some students may empathize with the character; for example, some students might consider the character's home life and whether or not the character's family had enough money to buy food. Other students might focus on the potential detrimental effects that stealing could have on the character's future (e.g., if caught, the character would have a criminal record, which could affect subsequent educational and employment opportunities). These differing responses and interpretations are not "right" or "wrong." They all have merit, and reflect the different levels of development among these students.

This variability in development can be viewed by teachers as either an instructional problem to be overcome, or an opportunity to educate and promote development across these domains. Most current views of psychological development acknowledge the social nature of development, and embrace the notion that development can be enhanced when youth are exposed to ideas, beliefs, and opinions of others that differ from their personal beliefs and experiences. Consequently, a teacher who understands, acknowledges, and embraces the diversity in development among their students is likely to treat this diversity in development across the four domains as an asset, and to support their students in understanding and learning from each others' viewpoints.

Conclusion

In addition to physiological development, adolescents are developing across an array of psychological domains. In this chapter, we briefly described the major developmental shifts that occur across these domains. We noted in particular that changes in each of these domains do not occur simultaneously. A student may be able to consider and discuss complex, abstract issues (i.e., the student might be in the advanced stages of cognitive development), but that same student might have no idea about what they want to do in the future (i.e., in the early stages of identity development). Moreover, in addition to individual differences in development within each adolescent, educators also must acknowledge that there is likely to be vast variation in development between their students.

We can support adolescents' learning and achievement when we are aware of the diversity in the trajectories at which adolescents develop across these domains. When educators understand these issues and can truly support all of their students by embracing and promoting development across the four domains, adolescents will benefit in countless ways.

Young adulthood

In recent decades, the path from adolescence to mature adulthood has lengthened. Increasing numbers of high school graduates attending college and graduate school have postponed career entry, marriage, and parenthood until the mid to late twenties or early thirties. Settling into mature roles and responsibilities has thus been delayed. These changes led [Arnett \(2000, 2015\)](#) to conceptualize the period of 18–25 years as emerging adulthood. This leaves the years of 25–40 as young adulthood proper, even though [Mehta et al. \(2020\)](#) recently conceived of the age range of 30–45 years as “established adulthood.” We consider these two divisions of young adulthood separately.

Emerging adulthood

Developmentally, the period of emerging adulthood is qualitatively unique, with its subjects engaging in more extensive identity excursions. Thus, emerging adults tend to remain self-focused as they delay commitments to careers and permanent responsibilities. [Arnett \(2000\)](#) notes that 40% of such adults move back into and then eventually leave their parents’ homes. Along with the approximately 60% of youngsters now attending college, of those who complete their baccalaureate education, about 33% then pursue graduate degrees. In the age range of 18–25 years, most subjects in Arnett’s study claimed that they were somewhere between adolescence and adulthood ([Arnett, 2001](#)). Developmentally, emerging adults believe that autonomy in decision making, financial independence, and the acceptance of personal responsibility for the self are paramount. As Arnett claims, these characteristics of self-reliance are assumed prior to making serious work commitments or assuming responsibility for others through enduring intimacy with a partner and parenthood (see also [Nelson, 2005](#)).

Extending [Erikson’s \(1968\)](#) depiction of identity development during adolescence, emerging adulthood is now the scene of identity exploration and development. In their quest for a vocational commitment, young adults in this period remain unstable while they seek to determine the nexus of their interests, talents, and values. Marking their exploration, job changes in the age range of 18–29 years average eight in number ([U.S. Department of Labor, 2012](#)). In recent decades, professional opportunities for young women now extend beyond the options of teaching or nursing, the dominant choices available during the middle of the twentieth century. Thus, for both genders in contemporary society, full identity development is deferred until professional development is complete.

[Arnett \(2000\)](#) has noted that the epoch of emerging adulthood applies best to societies that delay the beginning of mature adult roles. For example, the median age of marriage for women in industrialized societies is 26 while for women in developing countries it is 21 ([Arnett, 2000](#)). Parenthood in industrialized countries is often delayed until 30 years of age while it remains far earlier in less developed nations ([Arnett et al., 2014](#)).

Young adulthood

Once into young adulthood proper, several developmental markers appear. Self-concept and personality become more stable, commitments to a career or work role are realized, sequential intimacies mature into deep intimacy with a loved partner, and parenthood begins. Thus, young adulthood sees the culmination and stabilization of various forms of development that were previously in flux. We consider the key developmental attributes of personality, work engagement, and sustained intimacy with a partner.

Personality stability versus development

In recent decades, some personality theorists have held that just as the self-concept stabilizes during young adulthood, personality is fixed, typically, by age 30 (McCrae and Costa, 2008). This “plaster” position is countered by the premise of personality “plasticity.” This latter position accepts that certain aspects of genetics shape personality to some extent; however, adaptation to changing contexts alters personality over time. Indeed, changing roles and events (e.g., marriage, parenthood) have been shown to result in personality change. Denissen et al. (2019) demonstrated greater emotional stability, conscientiousness, and agreeableness during young adulthood. Others have noted that work requirements increase conscientiousness (Wagner et al., 2019).

Sociocultural changes have also been found to alter personality characteristics. For example, Roberts and Helson (1997) studied women over a span of 31 years and found that individualism and autonomy increased, particularly between 1960 and 1985. Autonomy increased as did national trends of heightened individualism and expectations of equality in work roles. A reciprocal association appeared in that assertiveness and individualism emerged from the feminist movement which then fostered increased autonomy in work environments.

It is important to note that the preponderance of personality development research employs the Five Factor Model (FFM) of McCrae and Costa (2008), specifically the attributes of extraversion, conscientiousness, openness to experience, agreeableness, and neuroticism. However, Srivastava et al. (2003) have claimed that the FFM is too “tidy” to comprise the entire range of personality attributes. In fact, a meta-analysis by Ackerman and Heggestad (1997) found that 19 personality characteristics were examined in 135 studies. Furthermore, in their content analysis of key personality journals, Cribb et al. (1992) discovered that more than 500 attributes were in evidence.

Identity and work commitment

Erikson (1950, 1968) established that identity is a lifelong process that is never fully complete. However, the beginning consolidation of identity occurs in young adulthood, largely due to commitments to the values, talents, and interests that coalesce into a work commitment. As Arnett (2015) noted, work commitments that previously took place in a person’s early twenties now occur in the thirties.

Identity development and evolution include learning about the self in work functions, roles, and contexts, just as one learns about the job itself. Meaningful work validates the self, connotes worth, and provides inclusion. Furthermore, some aspects of development and learning occur unconsciously. At best, adults who are immersed in work functions and the identity that these serve, tend to lose consciousness about themselves as they contribute effort in work roles. Thus engaged, persons exist in a time-out-of mind zone. As Erikson (1968) quoted from a letter of William James to his wife:

A man’s character (identity) is discernible in the mental or moral attitude in which, when it came upon him, he felt himself most deeply and intensely active and alive. At such moments there is a voice inside which speaks and says: “This is the real me!” (p. 19).

Sustained intimacy

As Alperin (2001) has held, the human’s desire for intimacy is innate. Intimacy sustains the self and exists in many relationships (e.g., relationships with a partner, with parents, and with friends). Young adults who develop close relationships with others are shielded from developing a sense of isolation or uncertainty about their place in society (see, e.g., Tanner and Arnett, 2016). The expression of intimacy in a sustained partnership with a loved other is the profound intimacy that begins in the years of young adulthood. According to Erikson (1968), beyond the mere sexual experiences that may precede actual genital maturity, intimacy depends, in part, on an established identity. This allows for unification with another and a deep commitment to the other. Together, these result in a blend of mutual commitment and a mutually fulfilling relationship despite the concessions and self-denial required. Such “mutual devotion” develops during young adulthood because psychosocial and physical readiness, together with acceptance of societal norms, prepare the way for a committed life together (Erikson, 1968, p. 137). In the best of circumstances, this supports species continuity through parenthood.

In young adults who are incapable of developing sustained intimacy with a loved partner, a “fear of fusion” and of engulfment by another inhibit the development of intimacy (Alperin, 2001, p. 137). In others, fear of abandonment by the loved other may preclude intimacy. In such circumstances, self-absorption with isolation is the prevailing resolution (Erikson, 1980).

Middle adulthood

At the outset, four points about middle adulthood bear emphasizing. First, it is important to note that, for 2019, the US Census Bureau estimated that 25% of the population was in the 40–59-year age group, roughly considered middle adulthood. At the far end of this spectrum, however, the term middle age is a misnomer. No one can reasonably expect to live until 118 years of age.

Second, there is no universal set of experiences that typify adult development during the midlife period. Because persons become more heterogeneous as they age, it is far easier to say what a group of 20 year-old emerging adults are like than it is to stipulate patterns of developmental change among a set of middle aged adults. Individuals interact with varying experiences and characteristics that are altered by, for example, socioeconomic status, health manifestations, culture, ethnicity, sexual orientation, diverse

work experiences, and unique relationships (see, e.g., Lachman, 2004). The only common experiences are women's menopause and, in both genders at midlife, a growing awareness of life's approaching end.

Third, middle adulthood is the least studied period of life (Lachman et al., 2015). This is partly because it is far easier to study children, young adults, and the elderly than to study middle aged persons who are actively engaged in their work and personal lives and are not seen in institutional environments such as schools or elderly care settings. Furthermore, Freud influenced students of psychological development to see the adult period of life as a barren stretch of time between genital maturity and death in which adults were expected to merely love and to work. To Erikson (1977), in Freud's thought, all one could expect of adults was the comparative absence of childhood "fixations," "guilt," "drives," and "repressions." The situation was compounded by G. Stanley Hall who, with his 1907 volume *"adolescence"* and his 1922 volume *"senescence,"* implied that there was little worthy of mention in the middle years. In his book titles alone, Hall excluded all of adulthood between adolescence and the deterioration of old age. Hall (1922) even held that "senescence starts in the early forties, or before in women ..." (p. vii).

It is also the case that only since the middle of the twentieth century have increases in longevity made it possible to conceive of a middle period of life prior to old age. For example, average US life expectancy was only 39 years in 1900. Only since the beginning of the current century has life expectancy exceeded 70 years of age.

However, even by the middle of the twentieth century when life expectancy had increased substantially, investigations into middle adulthood were rare. Looking to Psychological Abstracts, only in 1973 did the Abstracts first use the subject heading "middle aged." That was also the 1st year in which the Abstracts distinguished between young and middle adulthood as distinct periods of adult life.

Even when some notions of adult development were entertained, for a long period of time ideas about the adult were characterized by a product-like notion in which adults were conceived of as merely physically complete children. Development, when it was considered, charted mere chronology and event dependence. Collected years and marker occasions such as marriage, childbirth, and retirement were substitutes for developmental change.

Fourth, the term *development* is misleading for it implies only positive change. Departing from this, the psychological literature holds that human development is bi-directional throughout life. That is, growth and decline are seen across multiple domains (e.g., Lachman, 2004).

Recently, several large-scale studies have begun to explore this previously neglected period of life. For example, the Midlife in the United States (MIDUS) survey in 1995–1996 and 2011–2016 studied more than 7000 adults. It focused on psychosocial and physical health, and the ways in which middle aged persons work through midlife concerns (see Brim et al., 2004) and the Survey of Health Aging and Retirement in Europe (SHARE) randomly selected 27,500 adults over the age of 50. Its concern was with relationships between adult children and their parents (Dykstra and Fokkema, 2011). Surveys such as Health and Retirement Study (HRS), the English Longitudinal Study of Aging (ELSA), the German Socioeconomic Panel Study (GSOEP), Household Income and Labor Dynamics (HILDA), and the Midlife in Japan (MIDJA) study have also included middle aged adults (Infurna et al., 2020).

Midlife: a bridge period of positives and negatives

In many respects, midlife stands as a connecting period of life. It bridges early adulthood with old age, is a link between positive development and eventual decline, and connects the generations. It is also a period of heightened responsibilities and control, typically one in which earnings crest, control is exerted in the work realm, and self-confidence is high (Lachman et al., 2015).

Arnett (2018) described this period of life as one in which adults are "happily stressed." In his study of 834 US middle agers, most reported a peak in well-being compared with earlier adulthood. The top sources of pleasure were those of relationships with adult children (88%), hobbies or leisure pursuits (86%), and travel or holidays (82%). The primary sources of stress were financial issues (62%), work concerns (51%), and personal health (42%). Based on data from the Midlife in the US (MIDUS) survey, Lachman et al. (2015), study participants reported similar experiences. They related more positive than negative emotions, heightened autonomy, good relationships, and satisfaction with life. Gains in control were held as positive, knowledge and experience peaked, and, in general, difficulties were largely offset by growth and mastery.

While middle age is largely reported as a period of significant life satisfaction, anxiety and depression peak during this epoch (Infurna et al., 2020). This is especially the case for women, for those who claim Lesbian, Gay, Bisexual, and Transgender status (Brody et al., 2018), and for those of lower socioeconomic position (Infurna et al., 2020). Unsurprisingly, middle aged adults of lower socioeconomic position report more difficulties such as unemployment and financial difficulties. Low socioeconomic status has been associated with heightened psychological and medical problems and with more disabilities (Fingerman et al., 2018; Conger and Donnellan, 2007; Reiss et al., 2019). Many of those who had experienced childhood adversity (e.g., poverty, abuse, sub-par parenting, parental death) also show difficulties in middle age (Lachman et al., 2015). Such childhood difficulties are correlated with diminished mental and physical health at midlife as well as cognitive and interpersonal problems (Conger and Donnellan, 2007; Infurna et al., 2020; Reiss et al., 2019).

In recent decades, emotional and monetary support of adult children and aging parents has led middle agers to experience stress. Middle-aged adults are caught in the middle. Well-being is adversely affected by the multiple responsibilities entailed, particularly when aging parents or adult children of middle agers experience financial, emotional, and physical problems (Fingerman et al., 2018). Infurna et al. (2020) have termed the phenomenon "double- and triple-duty caregiving" (p. 474). In 2018, Mason held that 40 million US caregivers provide such care and support. This estimate may be low, in that the National Alliance for Caregiving has estimated that 65.7 million Americans currently serve as caregivers for disabled or ill family members.

Generativity

In his second edition of *Childhood and Society*, Erikson (1963) first wrote about the polarity of generativity versus stagnation, self-absorption, reactivity, and narcissism. Erikson held that generative adults focus their efforts on concern for others and for the products they create in personal and work domains. Generativity includes “procreativity, productivity, and creativity,” actions directed toward fostering the positive development of those who will follow (Erikson, 1982, p. 67). In caring for children and grandchildren, mentoring others, and engaging in civic commitments, middle aged adults sublimate their own needs in service to others, thus showing faith in species continuity. By “cultivating strength in the next generation,” they create a legacy that will survive them (Erikson, 1982, p. 67).

In the nearly 60 years since Erikson first coined the term, he and others have depicted generativity as a “universal human need and strength” (Erikson, 1969, p. 395). Erikson’s (1969) volume *Gandhi’s*.

Truth described the origins of militant nonviolence and generative concern for others in the life and work of Mahatma Gandhi. Since then, research has demonstrated that generativity is associated with a variety of positive characteristics and is a hallmark of positive psychosocial development at midlife.

Longitudinal studies have shown that generativity is correlated with positive psychosocial adaptation and with the use of developmentally mature coping mechanisms. Studies have also found an association between generativity and self-esteem (Blatny et al., 2019), with life satisfaction and subjective well-being, and with self-efficacy. Generativity is negatively correlated with neuroticism (Newton et al., 2014).

Cognitive developments in midlife

As for other characteristics, it is once again important to emphasize that there is substantial variability in cognitive changes among middle aged adults. That said, most investigators have found that cognitive ability is stable until 60 years of age (Diehl et al., 2020; Schaie, 2013). This includes vocabulary, accumulated knowledge, and semantic memory (Irwin et al., 2018; Salthouse, 2009). The exceptions are speed of processing and performance, reaction time, and numerical ability, all of which show some decline during the middle years of life, largely in the sixth decade (Diehl et al., 2020; Irwin et al., 2018). Greater distractibility also tends to manifest in some during the middle years.

Some studies have found that cognition is either stable or enhanced during the middle years. For example, cognitive functions that depend on experience often improve (Lachman, 2004). Furthermore, although some middle-aged adults express concerns about memory declines, research findings dispute this tendency (Lachman, 2004). In fact, any cognitive declines that occur are gradual and are offset by improvements in reasoning and vocabulary (Willis and Schaie, 1999).

Many experts associate high socioeconomic circumstances in childhood, high cognitive ability in childhood, and early education as protective against cognitive decline during mid-life (Brayne, 2007; Richards et al., 2004; Wang et al., 2019). Importantly, in 50% of middle aged and elderly adults cognitive ability has been portrayed as being due to childhood intellectual ability (Gow et al., 2011). More extensive education in youth is particularly important in the protection against mid-life cognitive deterioration.

Studies have found that engaging in work positions of high complexity (with data and people) maintains intellectual capacity (Staudinger, 2020; Wang et al., 2019; Singh-Manoux et al., 2005). In addition, cognitively demanding leisure activities (e.g., doing crossword and other word puzzles, playing chess, playing musical instruments) and ongoing learning foster better cognitive performance throughout middle and older adulthood (Singh-Manoux et al., 2005; Wang et al., 2019). Engaging in challenging tasks and experiencing novelty also maintain vitality and cognitive maintenance (Staudinger, 2020). As well, openness to experience, a key personality characteristic, buffers against intellectual decline (Staudinger, 2020). It is also the case that those with more education and continual learning fare better cognitively than those with limited education who may also restrict their learning (Diehl et al., 2020; Hughes et al., 2018).

Middle aged adults of higher socioeconomic position, due in part to their expansive social networks, and who also engage in complex jobs, show limited, if any, cognitive decline (Singh-Manoux et al., 2005; Wang et al., 2019). Of course, it may also be true that middle aged persons whose cognitive performance is high engage in activities that are more intellectually demanding. In general, among those who actively engage in stimulating activities, semantic memory (i.e., general knowledge, vocabulary, and word fluency) tends to decline far later in life (Irwin et al., 2018). Increases in semantic memory among such subjects typically increase until 60 years of age. Furthermore, although episodic memory (i.e., autobiographical material, statement recall, and the recollection of personally important events) tends to decline earlier than semantic memory, both forms of memory are preserved longer in persons who are cognitively able and who exhibit greater personal control in their lives (Robinson and Lachman, 2018; Tanner and Arnett, 2016).

Physical exercise also fosters the maintenance of intellectual abilities. Experts have suggested that physical fitness may lead to neurochemical changes that buffer against cognitive decline (Hultsch et al., 1999; Lachman et al., 2018). It is now known that neurogenesis (new neuron development), angiogenesis (new blood vessel development), and synaptogenesis (new synapse development) occur throughout life. It is also the case that aerobic exercise fosters these processes (Lista and Sorrentino, 2009).

Experts have also posed that, in some, cognitive decline is the result of disease processes and sedentary lifestyles. Hypertension, diabetes, high cholesterol, and obesity have all been implicated in intellectual deterioration (Singh-Manoux et al., 2012). Thus, some factors that persons can influence may result in cognitive maintenance or decline.

The myths of middle age: the mid-life crisis, empty nest stress, and menopausal difficulties

Jacques (1965) coined the term “midlife crisis” to depict what he observed in his analysis of the creations of artists and in patients’ changed productivity and their awareness of life’s finiteness. A classic portrayal of such a crisis is that of a middle-aged man who buys a sports car, divorces his wife, and has Botox injections to look younger. It appears that an actual crisis is largely a myth, in that studies have found that only 10%–20% of people report experiencing it (Infurna et al., 2020; Lachman, 2004; Wethington et al., 2004). It may be that the term “crisis” exaggerates something that occurs, but in a less traumatic manner. Some time ago, Neugarten (1968) held that middle-aged persons experience a change in their time perspective, moving from an assessment of “life since birth” to “time remaining to be lived.” The future is no longer limitless (Freund and Ritter, 2009). Earlier goals may have been reached and the midlife adult asks: “Is that all there is?” Or, goals now reached, the adult questions those goals and wishes he or she had pursued other dreams.

Another myth is that of stressful experiences due to the empty nest, of adaptations that must be made because children have left home. Presumably, mothers are affected more than fathers. It appears that many women consider this an opportune time to initiate new interests and to forge renewed bonds with their spouses, thus turning a potential trauma into advantages (Mitchell, 2006).

A third myth held sway for decades, the belief that menopause caused psychological difficulties due to the loss of fertility and because the phenomenon was but a preamble to death (Rossi, 2004). Currently, menopause is considered as a “benign event,” one that is not associated with eventual death (Rossi, 2004, p. 154). In fact, after menopause most women today still have one-third of their lives ahead of them. Some women have recently reported relief when menopause occurs, possibly because the childbearing years are now behind them. Furthermore, altered menopausal status has not been found to predict stress (Hedgeman et al., 2018). Wilk and Kirk (1995) have held that the menopause should be considered a developmental process and not a deficiency.

The world's population is aging. Globally, there are "727 million persons aged 65 years or over in 2020" ([United Nations Department of Economic and Social Affairs, Population Division, 2020](#), p. 1). In 2020, 9.3% of the population was over age 65 (p. 1). By 2050, the "number of older persons worldwide is projected to be more than double, reaching over 1.5 billion" (p. 1).

Because the older adult population is increasing, and learning is a lifelong endeavor, it is important to understand older learners and their learning. In this chapter, I discuss the definitions of "older adult." I touch on physical changes, namely differences in sight and hearing because these changes can profoundly affect learning. Additionally, I explore brain changes and the effects of exercise and cognitive training on the brain. Next, I investigate older adults' informal learning in daily activities and nonformal settings. Last, I conclude with observations about the literature on older adults in these areas.

The minimum age used to define an older adult varies. The age of 65 is typically chosen as a minimum age for later adulthood because "In 1889, the German Chancellor Otto von Bismark decided to set this as the age when people could receive social insurance payments" ([Whitbourne and Whitbourne, 2014](#), p. 8). Gerontologists divide older adults into three groups. Individuals ages 65–74 are "young-old," while those 75–84 are "middle-old" with age 85 and older considered "old-old" (p. 8). Some scholars use ages 50 or 60 as minimum ages to define "older adults." Most of the information presented in this chapter will concern adults aged 50 or older.

Physical changes

Individuals' appearances change in the skin, hair, body build, mobility, changes in vital functions, and diminishment in senses, including sight, hearing, taste, touch, and smell. Information about vision and hearing will be featured as a diminishment in these senses may significantly affect learning.

Vision

Although vision loss can occur at any age, most individuals with vision impairments are age 50 or older ([WHO, 2021](#)). Worldwide, in 2020, people aged 50 or older accounted for 78% of those who were blind (33.6 million of 43.3 million) and 70% of those with "moderate or severe vision impairment" (143 million of 265 million) (e133). Declining vision affects how people access and process information. The primary causes for vision loss in older adults include cataracts, glaucoma, macular degeneration, and diabetes-related vision complications ([Pelletier et al., 2016](#)). Cataracts occur when the eye lens becomes clouded ([Tyler, 2020](#)). Glaucoma causes irreversible damage to the optic nerve, which can result in blindness ([Pelletier et al., 2016](#)). Symptoms for age-related macular degeneration can include difficulties adapting to the dark as this disease affects the retina ([Pelletier et al., 2016](#)).

Fortunately, those with access to treatment for eye conditions can regain or maintain some sight. Researchers have shown that vitamin supplements may slow the progression of macular degeneration while eye drops and laser surgery can treat the progression of vision loss due to glaucoma (Pelletier et al., 2016). Cataract surgery does not require hospitalization, and the procedure takes less than an hour (Whitbourne and Whitbourne, 2014).

Hearing

In addition to having vision impairments, many older adults have hearing loss. Approximately 25% of those aged 60 or over experience “disabling” hearing loss worldwide (WHO, 2021, paragraph 6). Disabling hearing loss “refers to hearing loss greater than 35 dB (dB) in the better hearing ear” (WHO, 2021, paragraph 6). For comparison, bird calls are typically about 40 dB, and rustling leaves are about 20 dB (IAC Acoustics, 2021, Table 1). Common conditions related to hearing loss include age-related hearing loss (presbycusis) and tinnitus or ringing in the ears (Whitbourne and Whitbourne, 2014). Hearing aids can ameliorate some hearing issues and those who are hard of hearing use techniques such as looking directly at the person and turning down background noise (Whitbourne and Whitebourne, 2014).

Brain changes

In addition to changes in the senses, age-related brain changes affect memory, planning, learning, and decision-making. Older adults may have difficulty recalling names, find multitasking more challenging, and experience an inability to pay attention (National Institute on Aging, 2020). Brain changes include the shrinkage of the hippocampus, which affects one’s memory (Tyler, 2020). In addition, complex tasks take longer with age because there is a loss of myelin which connects brain areas (Tyler, 2020). However, new neurons continue to form brain-training exercises that help older adults “compensate for any age-related changes” (Erber and Szuchman, 2015, cited in Tyler, 2020, p. 1165). Following are studies on physical and cognitive training effects on the brain.

Studies on the effect of physical training on cognition

In general, physical training improves scores on tests measuring cognition. Data from two extensive studies have been analyzed: The Mexican Health and Aging Study (MHAS) ($n = 5853$) and the Korean Longitudinal Study of Aging (KLoSA) ($n = 5188$) to understand “the aging process in community-dwelling adults” aged 50 and older (Aarsland et al., 2020). Researchers conducted three (Mexico) and four-year (Korea) follow-up studies. In the MHAS, researchers asked people if they engaged in “vigorous exercise” 3 or more times a week, such as “heavy housework or sports” (p. 2). Participants in the MHAS were considered physically active if they participated in 150 min of this type of activity a week, and KLoSA participants were asked to report their physical activities. They were coded as “physically active” if they reported 150 or more minutes of exercise a week and “inactive” if they did less than 150 min a week. Cognitive functioning was assessed using the Cross-Cultural Cognitive Examination test (CCCE) for the MHAS and the Mini-mental state examination (MMSE) for the KLoSA. Physically active Korean participants scored better on these cognitive exams than their inactive peers. However, physically active Mexican participants did not score higher than their inactive peers. Researchers cited Mexicans’ poorer diet and lower average education level (less than six years) for lower cognitive test scores.

Scholars conducted a meta-analysis of 39 studies that had randomized controlled trials of physical exercise interventions in community-dwelling adults with an outcome measure of cognitive function (Northey et al., 2018). Participants were aged 50 or older. Thirty-six studies demonstrated that physical exercise, including “aerobic exercise, resistance training, multicomponent training, and tai chi” improved cognition (p. 154). Based on the findings, moderate aerobic and resistance training exercise is recommended for 45 min a day.

Similarly, Netz (2019) conducted a historical review of highly cited research studies on the effect of exercise on cognition. He found physical training, such as aerobic and strength training, improved brain blood flow, which improved cognition, while motor training, such as balance and coordination activities, directly affected cognition. The intensity of the physical exercise enhances the brain’s ability to adapt to change by forming more neural connections and ultimately improves cognition, whereas, with motor training, the complexity of the exercise improves cognition. Dual-task training that included cognitive demands in addition to physical or motor activity was more effective in preserving or improving cognitive functioning than a single task.

Kramer and Colcombe (2018) revisited their meta-analytic study of fitness effects on cognitive function. The original study (Colcombe and Kramer, 2003) reviewed 18 studies published from 1966 to 2001 that examined exercise effects on cognition in randomized controlled human trials with adults aged 55 or older. Exercise had the most significant impact on “executive control functions such as planning, scheduling, dealing with ambiguity, working memory, and multitasking” (p. 214). Since their review, more studies have examined how exercise results in brain changes. These studies have found that cardio fitness increases hippocampal

volume (Erickson et al., 2011, cited in Kramer and Colcombe, 2018, p. 214). In addition, aerobic training has improved parietal regions of an attention network that corresponded to improved performance on a selective attention task (Colcombe et al., 2004, cited in Kramer and Colcombe, 2018, p. 214). The authors note that most studies of change in brain structure are cross-sectional and observational, and there is a need for studies that establish causality between brain health and fitness.

Studies on cognitive training and improved cognition

Like physical training, some studies have shown brain training improves cognitive scores. For example, a 12-week chess training improved older adults' cognitive state, mood, and quality of life (Cibeira et al., 2021). Researchers recruited participants from day-care centers and nursing homes. Twenty-two participants over age 60 completed the study. Eleven participants spent 2 hours a week in a chess-training program, and the 11 participants in the control group had no intervention. Results showed "improved general cognitive status, attention processing speed, executive functions and QoL (quality of life)" for those trained in chess (p. 899).

Nguyen et al. (2019) conducted a meta-analysis of articles that examined the immediate and long-term effects of cognitive training on cognitive flexibility, inhibition, or working memory. Qualifying studies included a pretest and post-test and involved participants aged 60 or older with no neurological impairments, mild cognitive impairment, or diagnoses of dementia. Cognitive training occurred on a technological device, including a computer, gaming device, or mobile device. Researchers measured changes in attention, fluid intelligence, global executive function, language, memory, processing speed, and visuospatial ability. Sixty-one of the studies examined the immediate effect of training. Sixteen studies focused on the long-term effects of cognitive training (from three weeks to eighteen months). Cognitive training gains were significant in executive functioning, memory, and visuospatial ability from pretest to posttest.

Another meta-analysis of experimental studies on cognitive training showed mixed results (Sala and Gobet, 2019). Training improved working memory but did not improve other outcomes, such as verbal and non-verbal intelligence (Sala and Gobet, 2019) or enhance generalized cognitive function (Guye and von Bastian, 2017). The authors of the meta-analysis cautioned that many of the studies involved poor study designs and analysis and that placebo effects may have been responsible for some of the positive effects of brain training. They concluded that, at best, training on a particular task (working memory) may improve performance on that task but does not improve general intelligence (Sala and Gobet, 2019).

Studies on the effects of cognitive and physical training on the brain

Researchers have examined the effects of physical and cognitive training on the brain. Chapman et al. (2016) studied the differential effects of cognitive and physical training on the brain and behavior. Respondents completed cognitive training ($n = 18$) or physical training ($n = 18$) for 12 weeks. Participants learned strategies to improve their attention, reasoning abilities, and innovative thinking skills. The physical training program consisted of aerobic activity for 150 min a week. Exercise increased performance on memory tasks, whereas cognitive training enhanced executive function. Likewise, in a review of 19 articles on the effects of physical and cognitive training, researchers found that dual exercise training (e.g., aerobic training and weight training) interventions or physical-cognitive training interventions improved physical and cognitive test scores and that this type of training was the best intervention strategy (Levin et al., 2017). The authors noted that because the exercise interventions and test protocols were so diverse, it was impossible to see how these types of training affected individuals' performances.

In summary, physical training, including aerobic and resistance training and motor activities, has improved cognitive function (Aarsland et al., 2020; Netz, 2019; Northey et al., 2018). Cognitive training enhances attention processing and executive functions (Cibeira et al., 2021; Nguyen et al., 2019) and learning and memory. Researchers have found that cognitive training improves working memory but not other areas such as verbal or non-verbal intelligence (Guye and von Bastian, 2017) or general cognition (Sala and Gobet, 2019). Last, physical-cognitive training appears to produce the best results, but there needs to be improved testing protocols and interventions to understand better the associations between training and performance.

Cognitive changes affect learning, but how and where does adult learning occur? In the next section, I review the different types of learning and settings in which this learning occurs for older adults.

Older adult learning and education

Learning occurs in different settings. Formal education "refers to educational institutions including all levels of schools both private and public as well as specialized programs offering technical and professional training" (Merriam and Brockett, 2011, p. 15). Nonformal education is "any organized educational activity outside the established formal system ... that is intended to serve identifiable learning clientele and learning objectives" (Coombs, 1989, p. 11, cited in Merriam and Brockett, 2011, p. 15). Finally, informal learning is "generally unplanned, experience-based, incidental learning that occurs in the process of people's daily lives" (Merriam and Brockett, 2011, p. 14). Examples of this type of learning include reading a blog, viewing a TikTok video, or conversing with a friend. Since most older adults' learning experiences occur in nonformal settings and informal learning, I focus on these areas.

Informal learning

Informal learning occurs as adults navigate daily life. Examples of informal learning of older adults could include internet searches on leisure activities such as pickleball, crafts, or conducting genealogical research. In addition, informal learning includes self-directed learning. Individuals decide what they want to learn, which materials they want to use, how they want to engage in learning, and their self-evaluation (Knowles, 1975). An example of a self-directed learning project may be learning how to build a birdhouse. The learner decides whether to consult others on how to build a birdhouse. They may view YouTube videos, read books, or use any other methods they choose. The final product is a functional birdhouse. This section on informal learning discusses older adults' interaction with technology in their informal learning as technology is part of everyday life. Next, I focus on research on "Men's Sheds," which provide a casual learning environment for men, who typically come from a background in the trades, to gather and exchange information and work on projects informally. Last, I conclude the section with a discussion on older adult learning through volunteering and play.

Informal learning and technology

Technology permeates daily life. Its adoption for older adults' learning purposes is an area of research interest (Barrantes-Caceres and Cozzubo-Chaparro, 2019; Lai, 2020). Lai (2020) surveyed 238 older adult students, 55 and older, from 11 computer classes in central Taiwan. All participants used a smartphone or tablet for at least 30 min a day. Social influence (e.g., the opinions of their children and grandchildren), facilitating conditions (environmental factors that made use of technology easier), and performance expectancy (how the technology will help people achieve their goals), affected older adults' adoption of smartphones and tablets for learning. Older adults living with children were more likely to access the internet as the younger people can provide computer support and instruction (Barrantes-Caceres and Chaparro-Cozzubo, 2019). In addition, having a spouse or partner increases the amount of *time* older people spend on the internet (Barrantes-Caceres and Chaparro-Cozzubo, 2019).

Several studies concerned older adults' use of technology in their informal learning. Morrison and McCutcheon (2019) investigated older Canadians' online personal learning networks (oPLNs). oPLNs are "a collection of individuals and/or groups with whom you communicate, via the Internet, to engage in discussion, exchange information, and/or share resources to learn more about a hobby or interest" (Morrison and McCutcheon, 2019, p. 4). These researchers wanted to know who engages in online self-directed learning? What do oPLNs "look" like for these individuals (e.g., access, type, purpose)? How do these individuals use their oPLNs for informal self-directed learning? What is the perceived value of self-directed learning in their oPLNs? They surveyed 385 retired older adults who had oPLNs, and were 55 or older. The sample demographics included 57% male, most lived in Ontario, Canada, and had a household income of \$60,000 or more. Most respondents had used the internet for more than 15 years, with no significant difference in age and internet use.

Participants reported communicating with their oPLNs via email, Facebook, blogs, Google plus, and video conferencing, with email being the most common way to communicate (Morrison and McCutcheon, 2019). The purposes for using oPLNs included wanting to learn new things (90.9%), learning from others (73%), sharing knowledge (28.8%), "to learn by interacting with others" (45.7%), (p. 8), and "talking with others about interests or hobbies" (39.5%). (p. 8). Respondents were most likely to access and share websites for information. Nearly 73% strongly agreed or agreed that they "felt a sense of community with other learners in their oPLN" (p. 9). In addition, 86% said that members of their oPLNs provided expert knowledge. Younger participants (age 55–64) were more likely than the older participants (age 75 and above) to seek information online actively.

Older adults may also access the internet via a mobile device. In a literature review that examined the informal learning of older adults using mobile devices, Jin et al. (2019) reviewed 28 studies that met the following criteria: (a) appeared in a peer-reviewed journal, (b) written in English, and (c) published between 2005 and 2017. The 2005 date was chosen because wireless mobile communication became more prevalent, and data speeds increased. Several themes emerged. People engaged in health-related self-directed learning on their mobile devices. Individuals shared information about their health concerns and used mobile applications to monitor their fluid intake, weight, exercise, memory improvement and meditation. Respondents generally had positive attitudes toward using technology, and they saw the benefits of using mobile educational applications. However, they wanted to be assured of privacy, needed help setting up the devices, and wanted "easy access to continuous tutoring and instructional manuals" (p. 130). Older adults use mobile devices to communicate with others, including intergenerational communication. Studies showed the potential for collaborative learning by seniors using mobile devices. Participants shared information and commented on video content. The authors encouraged more research on specific cohorts of older adults (e.g., young-old (65–74), middle old (75–84), and old-old (85 and up) (Jin et al., 2019).

Scholars have also studied the informal learning of older adults on social media. Ebardo et al. (2020), for example, wanted to know why older adults used Facebook. The researchers collected 1707 posts between February and June 2020 from a Facebook community of 71,133 Filipino older adults in the Philippines (Ebardo et al., 2020). The most prominent theme was staying healthy. People discussed their routines for staying healthy and solicited advice when they had a health crisis. Second, individuals discussed staying safe from weather-related events. Third, they discussed caring for family members and maintaining relationships through COVID-19.

Older adults also find health-related support groups online. Litchman et al. (2018) conducted in-depth interviews with 20 United States Baby Boomers from a diabetes online community (DOC). Nine participants were male, with 11 were female; 14 participants possessed a bachelor's degree or higher, and 19 of the 20 identified as White. Most participants had Type 1 diabetes.

Participants used the DOC to learn about and manage diabetes, obtained emotional support from DOC members, and DOC "elders" served as role models and resources for less experienced members. Older members enjoyed giving back to the community. In summary, the DOC filled knowledge gaps and helped with the day-to-day management of diabetes.

Men's sheds

Men's Sheds originated in Australia in the late 1990s (Golding, 2015). These settings provide informal learning in a social, community setting for "older, typically retired, and sometimes isolated men" (Golding, 2011, p. 105). Activities at each Men's Shed vary according to men's interests, but generally there are places for hands-on activities and socialization (Carragher and Golding, 2015). Technology can be informal learning in Men's Sheds, although typical projects include woodworking and other trade-related activities. While Men's Sheds are open to all, this setting has been shown to appeal to older men with vocational schooling and less formal education (Golding et al., 2007). In this setting, men are not "treated by the organization, or by the women involved as customers, patients, students or clients from negative, deficit or ageist models" (Golding and Carragher, 2015, p. 104). Instead, they make friends and socialize, gain a sense of belonging (Carragher and Golding, 2015), feel increased self-worth, increased physical fitness (Crabtree et al., 2018) and feel less isolated (Nurmi et al., 2018). Attendees are both teachers and learners (Nurmi et al., 2018).

Recently, scholars have explored the effect of Men's Sheds on men's health and wellbeing. Kelly et al. (2019) provided a logic model of health and well-being outcomes of Men's Shed's activities. Their model had five components: interventions, mediating variables, intermediate outcomes, long-term outcomes, and results in physical health and well-being. They reported interventions found in studies, including providing skills and education, socialization, and the inclusivity of Men's Sheds spaces. A second model component, mediating variables, included increased skills, physical movement, improved social networks, improved health literacy, and decreased alcohol and drug use in favor of shed activities. Third, intermediate outcomes included increased fitness, motivation to leave the house, better social bonds, health-seeking behaviors, improved family relationships, and increased feelings of security and safety. Long-term outcomes were listed as increased confidence, decreased socialization, increased feelings of belonging, happiness, enjoyment, with less anxiety and feelings of depression. The last component of the model resulted from improved physical health, mental health, and social well-being. The authors provided an observed pathway to physical health: (1) The men's shed providing opportunities for physical activity increased physical movement—improved fitness—improved physical health. The authors developed "a logic model showing how Men's Sheds may influence health and well-being" but state, "There is a lack of reliable and systematic evidence of the health and well-being outcomes of shed activities" (p. 1155). Few studies included demographic information, and "Associative relationships between factors such as employment status of marital status and health and well-being outcomes are under-explored" (p. 1155). Areas of concern include a lack of exploration of contextual factors such as a rural location or levels of deprivation and subsequent links to health inequalities within communities.

Further, many studies were qualitative and had small sample sizes. The authors call for more quantitative and mixed-methods studies and longitudinal approaches. Subsequent studies have confirmed these health-related findings, such as increased mobility, decreased alcohol use, and improved health literacy (Kelly and Steiner, 2021). Some authors have answered the call for an expansion of research on the men's shed idea by detailing the development of women's sheds (e.g., Golding et al., 2021).

Intergenerational learning can also occur at Men's Sheds. Misan et al. (2018) examined the intergenerational learning between women college students majoring in Occupational Therapy and older men. College students conducted informal information sessions on cooking, exercise, and diet. Men participated in lawn bowling and a health check. The older men reciprocated by informally discussing the use of hand tools, portable power tools, and basic wood construction and finishing techniques. The men were happy to share their skills with the much younger women, building rapport.

In a study that examined how Men's Sheds could be marketed, researchers conducted focus groups with 64 men with 57 of them being 55 years or older (Nurmi et al., 2018). Twenty-two men previously had attended Men's Sheds. Additional participants were recruited from community organizations, coffee shops, and through a one-day advertisement in community newspapers. Researchers conducted four focus groups: two with non-Men's Shed members and two groups of Men's Shed members. Men's Shed's members discussed the activities men are interested in and how marketing is done. Non-members provided opinions about the branding images they saw about Men's Sheds. Men recommended advertisements be placed at men's places of employment, in newspapers, and in the community to attract new members. Another idea was having a Men's Shed member invite others to the Men's Shed. Creating a welcoming atmosphere would also attract members (Nurmi et al., 2018). Men mentioned barriers to attendance, including traveling outside their own neighborhood, not speaking English as a first language, and health issues.

Older adults' informal learning through volunteering and play

Older adults also engage in informal learning in other venues. Researchers wanted to understand how older men learned through volunteer activities (Chen, 2016). Participants were retired men over sixty who volunteered for at least two years. The researcher reached out to the non-profit organization and used personal networks to gain participants. Seventeen participants between the ages of 63 and 93 were interviewed. Researchers used the constant comparative method to uncover themes.

The results indicated that volunteers became more knowledgeable, skilled, and wiser (Chen, 2016). The knowledge learned depended on the type of volunteering. A nursing home volunteer gained medical knowledge while a museum volunteer learned about local history, astronomy, and botany. Second, learners used their life experiences were a foundation for learning. They

learned new things or deepened learning from what they already knew. They learned by watching others, doing the activities, engaging in individual reflection, talking with other volunteers, and participating in formal training provided by the institution. For example, one man learned better interpersonal skills by reflecting on interactions with others. Individuals learned skills through formal courses or by sharing information with other volunteers. A third theme included participants believing that they learned differently through volunteering than in the classroom. They found the volunteer type of learning more practical than classroom learning.

Another area of interest was how older adult motorcyclists learned through play (Zacharakis, 2019). He used grounded theory to uncover themes. He interviewed six individuals over age 60 (5 men and a woman). Participants developed their motorcycle skills through reading magazines, participating in workshops and classes, and talking with other motorcyclists. A participant liked teaching his children and grandchildren to motorcycle. Another worked on his agility and balance in an obstacle course. He enjoyed competing on obstacle courses, socializing with others, and repairing bikes. Others looked at websites and read magazines to learn more about motorcycling. Zacharakis (2019) found that people seek additional information to improve their knowledge and skills about motorcycling. Learning through play was intrinsically motivated. In addition, the social nature of the hobby was essential to people. The author noted that this study confirmed Bandura's (1977) theory that people learn from observation and enjoy the social part of learning. Second, this is an example of informal learning where the learner oversees the teaching (Marsick and Watkins, 1990, cited in Zacharakis, 2019, p. 181).

In summary, informal learning occurs in our daily lives. First, an investigation of the benefits of informal learning in Men's Sheds shows men socialize, learn and exchange information, make friends, and feel valued (Carragher and Golding, 2015; Crabtree et al., 2018; Golding et al., 2007; Nurmi et al., 2018). Second, much informal learning involves technology. Older adults adapt to technology if they are encouraged by family members to do so, environmental factors are conducive to adapting technology, and if there is support for technical issues (Barrantes-Caceres and Chappro-Cozzubo, 2019). Third, the use of technology in informal learning shows that adults use a variety of technologies (e.g., Google, Email, blogs, videoconferencing) to share information to learn new things, learn from others, gain a sense of community, and share their hobbies (Morrison and McCutcheon, 2019). Last, older people learn information as volunteers at various organizations (Chen, 2016), and they learn specific skills and knowledge like how to motorcycle and the benefits of motorcycling.

Nonformal learning settings: universities of the Third Age, Osher Lifelong Learning Institutes, and Road Scholar

Informal learning can occur in nonformal settings. Although nonformal settings can include book clubs, knitting groups, and sports clubs, I focus on centers where adults can engage in nonformal learning, as this has been an area of interest for researchers. For example, universities of the Third Age (U3As), primarily found in Europe and Asia, offer older adults the opportunity to engage in largely non-credit courses of their choosing. Individuals in North America have Osher Lifelong Learning Institutes (OLLIs) and Road Scholar (formerly Elderhostel) that provide similar programming (Formosa, 2019). The term "Third Age" refers to the third life stage where individuals are retired (Vellas, 2019, p. 19).

The first U3A program originated at the University of Toulouse, France, in 1968, and its curriculum initially focused on "gerontological subjects," later focusing on "humanities" (Formosa, 2019, p. 8). Teachers favored the lecture approach, although students also participated in debates, field trips, and recreational opportunities. Nowadays, lecture offerings are diverse and include Tai Chi, history, philosophy, art, religion, law, economics, and natural sciences (Vellas, 2019). The French model is linked with universities, and experts make programming decisions rather than class participants (Vellas, 2019).

The U3A in the United Kingdom (UK) was founded in 1981 (Percey, 2019) and has approximately 450,000 members with 1057 U3As (U3Aa, 2021, paragraph 2). Unlike the top-down French model, the UK model has local groups engage in peer learning (non-credit). There is a myriad of courses. Subjects include astronomy, boating, chess, etymology, learning to be retired, mindfulness and meditation, and sociology, among others (U3Ab, 2021, paragraph 5). U3As around the world use some variation of the French and British models. Countries with U3As include Iceland, Italy, Germany, Malta, Poland, the Russian Federation, Spain, Sweden, Australia, China, Lebanon, Malaysia, New Zealand, South Korea, Taiwan, and Thailand (Formosa, 2019).

In the United States, Osher Lifelong Learning Institutes and Road Scholar provide nonformal education for older adults. Osher Lifelong Institutes are associated with colleges and universities offering non-credit courses to adults aged 50 or older (Bernard Osher Foundation, 2005, paragraph 2). There are 124 OLLIs in the US (Bernard Osher Foundation, 2005 paragraph 2). Course offerings vary by Institute and include lectures by faculty, community experts, and OLLI members (University of Oregon, 2021). https://osher.uoregon.edu/about/types_of_courses.php (paragraph 2).

In the United States, Road Scholar (formerly Elderhostel) was founded in 1975 as a "not for profit education organization" (Road Scholar, 2021a, paragraph 1), with the first programs occurring at college campuses in New Hampshire (Road Scholar, 2021a, paragraph 2). Initially, the Elderhostel program offered courses to people aged 60 or older at colleges in New England. Road Scholar, 2021c, paragraph 4). By 1980, all 50 US States had programs, and by 1981 the organization had its first programs outside the United States (Road Scholar, 2021a paragraph 4). Currently, Road Scholar offers "5500 learning adventures in 150 countries and all 50 [US] states, serving more than 100,000 participants per year," and the program is not tied to college campuses (Road Scholar, 2021b, para. 5). Programs are open to all ages but typically attended by those aged 50 and older.

Demographics, participation and participants' interests at OLLIs and U3As

Researchers investigated various aspects of OLLIs, Road Scholar programs, and other Learning in Retirement centers. An area of focus has been on member profile differences (Lee et al., 2018), participation patterns (Truluck et al., 2010), members' experiences at OLLIs (Talmadge et al., 2019), barriers to age-friendly universities (Hansen et al., 2019), and membership characteristics (Hansen et al., 2016). Membership characteristics remain similar across studies. The typical OLLI or Learning in Retirement Center participant is a highly educated White woman. At least two-thirds of participants are women (Hansen et al., 2019; Truluck et al., 2010). At least 79% possess a bachelor's degree or higher (Hansen et al., 2019; Truluck et al., 2010). Those aged 60–74 comprise the most significant membership (Lee et al., 2018). Liberal arts, public policy, and current affairs courses are popular (Hansen et al., 2016; Lee et al., 2018; Truluck et al., 2010). Barriers to full participation in OLLI programs related to time, cost, transportation, and issues related to health, hearing, and physical mobility (Hansen et al., 2019). Racially, only 5.24% of OLLI participants identify as “non-White,” with “2.66% identifying as African American” (Hansen et al., 2019, p. 233). Race and the percentage of individuals with college or graduate degrees in these programs may be barriers to less-educated people and people of color. The authors recommend having OLLIs reach out to those who may not come to OLLIs because of unpleasant educational experiences (Hansen et al., 2019).

Some of the research and scholarship on U3As concerning older adult learning and education focuses on programmatic issues and/or benefits of U3As (de Maio Nascimento and Giannouli, 2019; Hachem and Vulopala, 2016; Ricardo and Porcarelli, 2019) and identity issues such as participants' concepts of old age (Camargo et al., 2018). Scholars analyzed U3A program models in various countries. For example, Brazil blends the French and British U3A models and offers formal courses through universities and extension courses on art, literature, health education, tourism and leisure, general knowledge, and foreign languages (de Maio Nascimento and Giannouli, 2019). Given Brazil's “intense body culture,” the U3A's focus on physical activities for older adults stands out. These courses benefit older adult participants and contribute to older adults' physical activity knowledge. In addition, older adults are part of university-conducted research studies that focus on action research and empowerment.

Hachem and Vuopala (2016) surveyed 461 older adults at a University of the Third Age in Lebanon to uncover the benefits and challenges faced by participants. Eighty-three percent were women, with 71.5% being between 50 and 69 years old. Cognitive benefits included gaining knowledge and intellectual stimulation. Social benefits included making friends, learning from each other, and belonging to a community. Psychological benefits included experiencing positive emotions. Participants' challenges included the use of lectures and the timing of sessions.

In summary, membership characteristics for OLLIs and Learning in Retirement centers tend to be middle-class, highly educated White women. There is a plethora of course offerings and adventures in these settings. Barriers to participation in classes include time (Hansen et al., 2019), and fewer people of color or those without a college education attend courses at these institutions (Lee et al., 2018; Truluck et al., 2010).

Summary and conclusions

Physical changes in older adults may affect how they process information. Changes to vision and hearing may be especially challenging. Glaucoma, presbyopia, and cataracts are common eye diseases that affect adults worldwide (WHO, 2021). However, treatments for glaucoma, including eye drops and laser surgery, may be options for those with glaucoma and, similarly, hearing loss is common in older adults, including presbycusis and tinnitus (Whitbourne and Whitbourne, 2014). Hearing aids can help with hearing loss.

In addition to vision and hearing changes, brain changes also occur. Multitasking becomes more challenging, and brain areas, including the hippocampus, may shrink (Tyler, 2020). However, physical training has improved cognitive function (Aarsland et al., 2020). Mental training has been shown to improve executive functioning, memory, and visuospatial ability (Nguyen et al., 2019). Cognitive training improves attention processing and executive functions (Nguyen et al., 2019) but not other areas such as verbal or non-verbal intelligence (Guye and von Bastian, 2017) or general cognition (Sala and Gobet, 2019).

There will be advancements in medical science. More will be discovered about the older adults' brain and maintaining and improving cognition through physical and cognitive exercises and diet. Additionally, scientific advancements in treating eye diseases and hearing loss may allow older adults to participate in learning activities more fully in the future.

Most adults engage in informal learning. This learning can occur in everyday life or nonformal settings such as knitting groups or organizations like Universities of the Third Age. (U3As). Recently, scholarship has focused on participation in OLLIs or U3As or Learning in Retirement Centers (Truluck et al., 2010), membership profiles (Hansen et al., 2016; Lee et al., 2018), and demographics of organizations (Lee et al., 2018; Truluck et al., 2010) that cater to older adults such as U3As, Road Scholar and Osher Lifelong Learning Institutes. People of color and individuals with lower levels of education are less likely to attend these learning opportunities. However, the older, less educated man may be interested in the informal learning opportunities in Men's Sheds (Carragher and Golding, 2015), where men informally gather to work on hands-on projects and exchange information about various concerns.

In addition to continuing research on the informal learning of older adults in nonformal settings, researchers should focus on more clearly defining the term “older adult” in their research. They should also seek to understand the learning experiences of older adults marginalized by gender, sexual orientation, ability status, class, and race/ethnicity. Finally, taking a more critical look at the influence of social capital on the learning experiences of older adults may be in order. Learning is lifelong, and as the population of older adults increases worldwide, more researchers need to be interested in various aspects of this population.

Education has been linked to many advantageous health outcomes (e.g., Ross and Wu, 2006). In the present chapter we will address the question of whether formal education, which typically occurs in childhood and early adulthood and is indexed by years of completed education or educational qualifications, influences “neurocognitive aging”. That is, will education impact the decline in integrity of the brain (e.g., shrinkage of the brain; *atrophy*) and cognitive functioning (e.g., *episodic or working memory*) that are characteristic for the normal aging process and become magnified in pathological aging, such as in neurodegenerative diseases that result in dementia? This question is at the heart of the broader issue of *modifiable risk factors*, an issue which currently is attracting considerable interest in the scientific community in relation to global population aging (Livingston et al., 2017). There is convergence from many longitudinal studies of cognitive aging for marked heterogeneity in the rate of decline in cognitive functions such as episodic memory (Nyberg and Pudas, 2019). Similarly, there are marked individual differences in brain aging, such that some older adults manifest major decline whereas other present with more “youth-like” brains, and the influential *brain-maintenance* theory states that relative lack of brain pathology constitutes the primary determinant of well-maintained cognition in aging (Nyberg et al., 2012). The question of which factors promote maintained brain and cognition in aging is currently intensively researched, and some consistent findings have been reported for both genetic factors (e.g., Josefsson et al., 2012; Lin et al., 2017) and lifestyle activities such as physical activity (Dunas et al., 2021). Critically, theoretical models also include educational attainment as a predictor of rate of neurocognitive change in aging (see e.g., Cabeza et al., 2018).

The educational attainment of people is, in theory, modifiable, but to qualify as such a factor the underlying assumption is that education has a *causal* effect on aging of brain and cognition. However, educational attainment may also be viewed as an outcome of preexistent differences in brain and cognition between people. In addition, associations between educational attainment and aging of brain and cognition may stem from external factors, such as parental socioeconomic status, that have independent effects on both aging and education. In the course of the chapter, we will highlight evidence (or the absence of evidence) for these alternative accounts.

How could educational attainment – in theory – impact brain and cognitive aging? This “million-dollar question” is often answered by arguments that education contributes to building a “reserve”. Based on such a reserve, some individuals are assumed to be better than others at tolerating or compensating for brain insults conferred by aging, damage, or disease. The reserve concept has a quite long history (Blessed et al., 1968; Rothschild, 1937), but more modern conceptualizations distinguish between a more passive *brain reserve* versus a more active form of *cognitive reserve*.

A higher *brain reserve* could mean that some individuals from childhood and onwards in life have bigger brains and/or a higher proportion of large neurons in the brain (cf. Katzman et al., 1988). Thereby, compared to individuals with less brain reserve, it will take longer for the high-reserve individuals to reach a threshold for functional impairment – even if their change functions (slopes) are similar (Fig. 1A; Y-axis displays a metric of brain reserve). If education has an effect on building a brain reserve, then people with higher educational attainment can be predicted to have bigger brain (and better cognitive performance) after the end of formal education, but thereafter show similar rates of change of brain and cognition as those with lower education. In other words, by having more brain tissue (higher intercept), a certain amount of brain atrophy is better tolerated in aging in high-reserve individuals as compared to low-reserve individuals before the atrophy translates into behavioral problems. (the threshold for cognitive impairment is reached at an older age for individuals with higher brain reserve).

The active form of reserve, *cognitive reserve* (Stern, 2009), emphasizes functional attempts at *compensating* for negative brain changes. By this view, individuals with a higher cognitive reserve can use alternative cognitive strategies to cope with the challenges induced by a certain level of brain atrophy, whereas individuals of the same age but with lower cognitive reserve will show cognitive impairment for a similar level of atrophy (Fig. 1B, left panel). Thus, high cognitive reserve is not considered to protect against age-related brain atrophy, but instead reduce the negative influence of such brain changes on cognition as compared to individuals with less cognitive reserve. It should be noted that it remains a possibility that higher education and, by inference, higher cognitive reserve will confer a cognitive advantage across age and atrophy levels (Fig. 1B, right panel). That is, in particular for more challenging cognitive tasks, it may well be that the advantage of high cognitive reserve is not only manifested when a certain atrophy

Fig. 1 Theoretical models of how education could relate to brain and cognitive status in older age (see text for details).

level has been reached. Still, the net result is the same – a given level of atrophy translates earlier into cognitive impairment for individuals with low education and reserve (i.e., the blue line crosses the threshold for impairment earlier in both the left and right panel of Fig. 1B).

The question of how education could impact brain and cognitive aging could – in theory – also reflect a situation where higher education actually slows the *rate* of brain aging. This scenario is hypothetically illustrated in Fig. 1C, where individuals with higher education (red line) have a slower rate of brain change than individuals with lower levels of education (blue line). Thus, this scenario, in contrast to those in Fig. 1A and B, holds that brain changes in aging may actually be slower for individuals with higher education. Thereby, at a given age, there will be less brain atrophy for individuals with higher education, which translates into a cognitive advantage.

Next, we turn to reviewing the state of the art regarding if and how educational attainment is associated with neurocognitive aging. The different scenarios outlined in Fig. 1A–C will feature in discussions of brain aging as well as cognitive aging, and in a concluding section we offer a synthesis and outline some issues for future studies.

Education and brain aging

Brain aging is an umbrella term that spans several changes within the central nervous system that tend to increase in frequency and magnitude as individuals age. Brain aging is examined at many different scales, ranging from the macroscopic whole-brain level to the microscopic sub-cellular level. Influences of education on human brain aging, in principle, could occur at any of these levels and they could also be expressed at multiple levels simultaneously. The majority of studies related individual differences in educational attainment to different kinds of data acquired by means of magnetic resonance imaging (MRI). MRI is a highly versatile tool that offers detailed examination of structural and functional brain integrity. Age-effects on brain structure and function are found for most MRI measures and regions, but with substantial heterogeneity with regard to region and shape of trajectories (Nyberg et al., 2022). In addition, there is growing consensus for marked heterogeneity within the older population, such that some individuals show a faster-than-average rate of brain aging whereas others present with a relatively well-maintained brain in older age (Nyberg et al., 2012). In view of such heterogeneity, numerous studies have explored genetic and lifestyle factors that may predict individual differences in brain aging (Nyberg et al., 2020).

Studies of educational attainment have yielded mixed results regarding if and how it relates to individual differences in brain aging. For example, Rzezak et al. (2015) compared older adults (around 70 years of age), who had less than 4 years of education, with a group with an average of 10 years of education. The results identified one frontal region with significantly greater gray matter volume in those with higher educational attainment, and another region showing a similar trend. Some other studies reported the opposite direction of results, with thinner cortex in high-compared to low-educated older adults (Pillai et al., 2012), other studies found that education is associated with higher cortical thickness in some areas but lower in other areas (e.g., Habeck et al., 2020), and still other studies found no relation of educational level on individuals' brain age (Dunas et al., 2021; but see also Steffener et al., 2016). Nevertheless, several studies have reported a similar results pattern as in Rzezak et al. (2015), with larger brain metrics in individuals with higher levels of education. A large-scale example of the latter comes from a study of 19,793 individuals in the UK Biobank (UKB) study (Nobis et al., 2019), which reported that higher education levels were associated with larger hippocampus volumes, albeit with a very small effect size (0.07 Standard Deviations; SD).

The studies mentioned above, as well as the majority of studies in the field more generally, based their conclusions on *cross-sectional comparisons*. That is, brain integrity of a group of older adults with high education was compared with that in a group of older adults with lower education. While a finding of a larger brain volume in the group with higher education might be interpreted to reflect reduced rates of brain aging, an alternative interpretation is that the difference is not specific to older age and aging *per se*. That is, it is quite possible that the brains of the high-education individuals were larger already in childhood and adulthood (cf. Cox et al., 2016). To be able to say more conclusively that individuals with higher education display slower brain aging, *longitudinal designs* (i.e., repeated measurements of the same individuals over time) is vital. Such designs provide information on within-person changes over time, and thus offer a stronger test of whether a factor like education has any influence on brain aging. To date, there are only limited relevant longitudinal data on this topic.

Raz et al. (2005) published a seminal study in the field in which five-year change in the regional volumes of healthy adults were analyzed. The statistical approach was latent difference score modeling, and the analyses involved 72 participants. The results revealed significant volume reductions in all examined brain regions (except the primary visual cortex, where little change was expected). In most of these regions, there were significant individual differences in rates of change. To some degree, those individual differences related to hypertension, but no support was obtained that higher levels of educational attainment were associated with reduced brain shrinkage.

In another study, Pillai et al. (2012) investigated 91 healthy controls and 140 individuals with Mild Cognitive Impairment (MCI) from the Alzheimer's Disease Neuroimaging Initiative (ADNI). Analyses of one-year atrophy rates revealed a significant effect of diagnostic group (more atrophy for the MCI individuals), but the analyses provided no support for a relation between regional shrinkage and higher (18 or more years) or lower (13 or less years) educational attainment.

A final example of a longitudinal study of the influence of educational attainment on brain aging (MRI measures of brain atrophy) comes from a recently published paper (Nyberg et al., 2021). In a first step, regional samples from the Lifebrain project (N = 735; 1844 scans) were examined with education coded as a continuous variable. In good agreement with prior observations, longitudinal analyses revealed significant atrophy in several cortical regions and also in the hippocampus. Critically, however, level of education was not associated with rates of cortical or hippocampal change. In a second, replication step, similar analyses were conducted on data from the UKB (N = 1289; 2578 scans). As in the Lifebrain analyses, longitudinal analyses of the UKB data revealed marked atrophy in the cortex and in the hippocampus, but again educational attainment (college/university vs. non-university) was not associated with rates of change. Thus, based on 4422 observations and a longitudinal coverage up to 11.2 years, it was concluded that higher education does not slow down brain aging (see Fig. 2).

Fig. 2 Cortical volume decreases with age in both high and low educated people. Although cortical volume is slightly higher in those with high education, the rate of change is the same. Data source: Lifebrain and UK Biobank. Credit: Fredrik Magnussen.

Despite the lack of influence of educational attainment on brain change, it still remained a possibility that education would be associated with volume itself (i.e., an intercept but not slope effect). In both analyses of data from Lifebrain and UKB, some limited support for this hypothesis was obtained in that higher levels of education were found to relate to a larger cortical volume (Fig. 2). At the regional level, the highest between study overlap was located near the left central sulcus. In addition, some study-specific cross-sectional associations were observed in both studies. As suggested by the above mentioned Nobis et al. (2019) UKB study, analyses based on a greater number of observations will likely reveal additional intercept effects (e.g., in the hippocampus), but with limited effect sizes. Thus, modest education effects on brain volume may exist, but such a relation does not necessarily reflect a direct and causal influence of education on brain size but may instead be driven by shared genetic effects (cf. Grasby et al., 2020).

Regarding other metrics of brain aging, some of the above-mentioned studies included MRI measures of *white-matter integrity*. Raz et al. (2005) included assessment of changes in frontal and parietal white-matter integrity in their analyses, and no evidence was found for a relation between rates of change and education. Relatedly, Dunas et al. (2021) included various MRI white-matter images in their computation of “brain age” but found no relation to education. A study by Dufouil et al. (2003) examined MRI measures of small brain lesions (white-matter hyperintensities) and found a relation of higher white-matter lesion and lower cognitive functioning on some tests in individuals with low, but not high, education. The authors concluded that their findings indicate that education modulates the consequences of lesions on cognitive performance. However, as discussed above, as this was a cross-sectional study, it cannot be ruled out that the low-educated individuals with high lesion load and lower cognitive performance actually had a lower cognition already in younger age (for example due to genetic and/or lifestyle factors underlying vascular risk).

The structural brain measures considered so far, reflecting gray- and white-matter structural integrity, may most closely relate to the notion of passive brain reserve as discussed above (Fig. 1). Functional MRI (fMRI) offers a means to examine task-related brain activity, indirectly indexed by brain blood flow, while participants are given various cognitive challenges. In addition, fMRI allows measurement of resting-state connectivity, which might be seen as reflecting the status of the *functional connectome* in aging and disease (for a review of fMRI at rest and task, (see e.g., Raichle, 2010)). As such, fMRI may more directly relate to active cognitive reserve, and several relevant cross-sectional studies have been published (see e.g., Anthony and Lin, 2018; Steffener and Stern, 2012). Some studies specifically examined educational attainment in relation to fMRI responses, and some support has been found that education relates to fMRI measures (e.g., Chan et al., 2021; Kim et al., 2021). However, at present, convincing longitudinal evidence is lacking that individuals with higher education have altered fMRI response changes in aging compared with individuals with lower levels of education. Therefore, in view of demonstrations of fundamental differences between cross-sectional and longitudinal estimations of age-related fMRI responses (Nyberg et al., 2010), we conclude that the current state of knowledge remains unclear regarding if and how education impacts functional brain activity changes in aging.

Education and cognitive aging

A positive association between educational attainment and cognitive performance is remarkably robust across age, gender, historical times, and societies (Lovden et al., 2020; Opdebeeck et al., 2015; Strenze, 2007). Focusing on cognitive performance in older age, Opdebeeck et al. (2015) reported an average association of around $r = 0.3$ between general cognitive ability and educational attainment. In other words, an individual with a university degree is expected to have an advantage of roughly 4–5 IQ points relative to an individual with a high school diploma (i.e., 5 fewer years of education). It might be expected that education is more closely related to so called crystallized cognitive abilities, such as vocabulary and academic knowledge, than to fluid cognitive abilities, such as

abstract reasoning and processing speed. However, the available meta-analyses do not support this prediction (Opdebeeck et al., 2015). It could also be imagined that the association between educational attainment and cognitive ability is not linear. For example, further education may have diminishing effects on performance at higher levels of education. Although a few studies have reported trends for such non-linear effects, the association remains positive also at higher levels of educational attainment (Kobayashi et al., 2017; Myerson et al., 1998).

In contrast to the lack of evidence that would allow for causal interpretations of any effects of education on brain integrity, there are solid results that speak to this issue for cognitive performance as an outcome (Ceci, 1991; Ritchie and Tucker-Drob, 2018). For example, researchers in several countries have used policy changes (e.g., increasing years of mandatory schooling) as an instrument for estimating causal effects of early schooling. This is possible because there is often regional variation in the timing of when such policy changes have been implemented. Typically, cognitive performance is analyzed in large samples of individuals that are affected by the policy changes and who have taken part in assessments of performance during military conscription. A meta-analysis of such studies indicate that effects of schooling on performance are sizable (about 1–2 IQ points per year of additional schooling) and do not differ in magnitude between crystallized and fluid cognitive abilities (Ritchie and Tucker-Drob, 2018). Because a main purpose of schooling is to convey forms of declarative and procedural knowledge, effects on crystallized cognitive abilities are clearly expected. However, schooling may also improve cognitive strategies and test-taking skills (Ceci, 1991) or support more and better abstract thinking (Flynn, 1984), and through these pathways it could affect fluid cognitive abilities. In addition, effects of education on cognitive performance could emerge if education acts to protect young individuals from hazards of not being in school, such as harmful effects (e.g., stress) of work environment (Lager et al., 2017).

Nevertheless, a causal effect of education is unlikely to be the only origin of the association between educational attainment and cognitive performance. There is ample evidence to indicate that an individual's educational attainment is partly the outcome of socioeconomic factors (e.g., parental resources) that operate throughout development in childhood. It is quite possible that these factors also influence development of cognitive performance. In addition to being an outcome of chances in life, educational attainment is also influenced by an individual's own behaviors (e.g., cognitive performance, personality) and by how the individual interacts with the sociocontextual chances that are available (Tucker-Drob et al., 2013). Cognitive performance is perhaps the most important of these individual factors: Reported correlations between general cognitive ability and scholastic achievement average around $r \approx 0.50$ (Johnson et al., 2009; Mackintosh, 2011). Many of the abilities and traits (e.g., cognitive performance) that are important for performance in school, and therefore also for educational attainment, are heritable. This helps to clarify the background to why scholastic performance (Krapohl et al., 2014), as well as educational attainment (Cesarini and Visscher, 2017; Davies et al., 2016), also are heritable. That is, parts of the association between cognitive performance and education are of genetic origin.

The complex interactions among abilities, sociocontextual factors, and education during development lead to an association between educational attainment and cognitive performance that remains into older age. Therefore, educational attainment is an important factor that influences when critical thresholds (e.g., functional impairments) are reached in older (see Fig. 1). It is not surprising, then, that educational attainment also is a powerful risk factor for dementia diagnosis (Sharp and Gatz, 2011; Xu et al., 2016). But is educational attainment also associated with change (i.e., the slopes) in cognitive performance in aging? The evidence for such an association is much more unconvincing than that observed for associations between educational attainment and levels of performance. In one study, the authors (Lipnicki et al., 2017) analyzed harmonized data from several longitudinal studies conducted in 12 countries (Australia, Brazil, France, Greece, Hong Kong, Italy, Japan, Singapore, Spain, South Korea, the United Kingdom, and the United States: total $n = 42,170$). The average estimates across the studies indicated that educational attainment had no noteworthy associations with changes in cognitive function. A weak association between education and change in memory (one year of education comes with less than 0.01 SD per decade of memory decline) was reported in another major recent analysis of over 11 000 older individuals taking part in the Survey of Health, Aging, and Retirement in Europe (Cadar et al., 2017). A comprehensive meta-analysis by Seblova et al. (2020) confirmed the general impression from these major studies. The point estimates of the average relationship between one additional year of education and cognitive changes were not statistically significant and they were very small: less than 0.001 SD per decade for episodic memory and reasoning, and less than 0.002 SD per decade for general intelligence and processing speed. Even if we take these effect sizes at face value we must conclude that they are of an unimportant size: Over two decades of decline (e.g., from age 60 to 80 years), the general magnitude of these associations comes with an effect on level of cognitive performance in older age (at age 80 years) that is of less than 1/10 of the importance as the association between education and level of cognitive performance in younger adulthood that was discussed earlier (Lovden et al., 2020). Reviews of the literature on changes in cognitive performance in individuals that are later diagnosed with dementia come to the same conclusion – there is no substantial evidence linking educational attainment to changes in cognitive performance (Lovden et al., 2020) (Fig. 3).

It is however noteworthy that there is a substantial heterogeneity across studies in the association between educational attainment and change in cognitive performance (Seblova et al., 2020). It may be that some substantial association may appear in some populations or societies. For example, effects of educational attainment on cognitive change may appear in samples of individuals who are poorly educated. No such pattern was however apparent in the reviewed meta-analysis. The roles of factors such as retirement, birth cohort effects, gender, and retest effects, that differ as a function of educational attainment, are also not fully understood. Studies also differ greatly in their treatment (inclusion vs. exclusion) of individuals with dementia, but studies aiming to address the effect of this treatment find no noteworthy differences (Lipnicki et al., 2017). It also possible that associations between educational attainment and cognitive change depend on equality in access to higher education. However, the meta-analysis by Seblova et al. (2020) showed no association between effect sizes and the Gini coefficient (a common measure of a country's

Fig. 3 Outcomes from studies examining the association between age-related change in episodic memory and education. The figure shows correlations (squares) reported for individual studies. The area of each square is proportional to the sample's weight in the meta-analysis, and the horizontal lines represent confidence intervals (see also the right-hand column for exact numbers). The red diamond shows the weighted effect of the meta-analysis. A positive correlation indicates that higher educational attainment is associated with slower cognitive decline. Adapted from Seblova, D., Berggren, R., Lovden, M., 2020. Education and age-related decline in cognitive performance: systematic review and meta-analysis of longitudinal cohort studies. *Ageing Res. Rev.* 58, 101005. <https://doi.org/10.1016/j.arr.2019.101005>.

inequality). Thus, if the heterogeneity of results across studies is genuine, then the sources of it remain unknown. In addition, any substantial association between education and change in cognitive performance could only be an exception, and not the rule.

In summary, the evidence available to date reveals that the association between educational attainment and cognitive changes in older age is typically unreliable and much less important for life in older age than the association between education and level of cognitive performance that arises during childhood.

Conclusion and outlook

Educational attainment displays a similar relationship to both aging of the brain and aging of cognitive performance. Education is robustly associated with level of cognitive performance, and to some extent with brain integrity, but there is no substantial evidence that neurocognitive aging, in terms of individual changes over time, is much affected by peoples' formal education in early life. The empirical pattern is not in line with theoretical ideas suggesting that education conveys a cognitive reserve (e.g., individual resources such as knowledge and cognitive strategies) that can be mobilized to uphold high levels of cognitive performance in aging. The pattern is also inconsistent with theoretical speculations suggesting that the health benefits that education is related to (e.g., better health care and loss risk behaviors such as smoking) significantly impact aging of the brain (and therefore cognition). Rather, the pattern of results is more consistent with a passive reserve account: Educational attainment is primarily related to late-life cognitive functioning by playing a role in the developmental processes that lead to differences in brain and cognition during early adulthood, and these differences persist into older age. Having said this, we note that the influence of education attainment on the association between aging-related changes in brain and cognition remains largely unaddressed so far. Estimating this effect in the future will be the critical test that can distinguish between the validity of alternative theories that have been proposed, with the cognitive reserve theory predicting such an effect, while the brain maintenance theory would predict an absence of such an effect. Recent efforts to harmonize large-scale longitudinal studies of changes in brain and cognition may allow, for the first time, well-powered tests of this fundamental question.

Introduction

Issues and perspectives in learning beyond initial schooling can be understood in terms of a triadic conception of lifelong learning, which is animated by the interplay between three dimensions: (1) educating for a more highly skilled and knowledgeable working population; (2) supporting personal development that activates inquiry and explores what life has to offer; (3) creating conditions for a stronger and more inclusive society (Aspin et al., 2012).

Furthermore, two analytical perspectives are pertinent in considering issues and perspectives. The first focuses on the social organization of learning. This perspective emphasizes adjustments to changed conditions in work and society and the need to address dysfunctionality in existing educational provision; the need for “flexibility,” and recognition of the prior and informal learning of adults. It recognizes the workplace and community as significant settings for learning, debating the characteristics of “learning organizations” or “communities of practice.” The second analytical perspective focuses on learning as a biographical process—the learning individual. It is predicated upon the multiple sources of evidence of the cognitive social, psychological and cultural dimensions of adult learning that have challenged deficit models that equate aging with cognitive losses (Formosa, 2019) and generated new insights into the expansion of adults’ capabilities through purposeful activity at all ages. This perspective recognizes the heterogeneity of adults’ learning, the conditions and opportunities that shape learning; the social structuring of the life course and the accumulation of risk and inequalities. At the same time, it keeps in view personal agency (Evans et al., 2013), reflexivity in learning, the significance of social networks and role of multiple forms of capital (O’Tuama, 2020, 2022).

The triadic conception is holistic in nature and represents a departure from approaches that translate the aims of personal development, higher skills and knowledge and enhanced social participation into competing modes and models. Interdependencies of the three dimensions of higher skills and knowledge, personal development and social participation are critical to the triadic conception; “if any one of the dimensions fails, the center cannot hold” (Evans, 2021, p. 350). A triadic conception is evidence-informed. We know, for example, that if education for higher skills and knowledge in the workforce is also accompanied by growing inequalities between the knowledge rich and knowledge poor, the conditions for the strong and inclusive society are undermined (Green, 2011). For the center to hold, wider distribution of higher skills and knowledge in the adult population is necessary, but is that sufficient for sustaining a stronger society? According to the triadic conception, not so; for a stronger and more inclusive society higher average levels of knowledge and skills have also to be accompanied by personal attributes of inquiry that support long-term learning engagement in changing circumstances: “strategies for workforce development and channels for enhanced social participation will not be sustainable in the longer term unless they are powered by curious and capable people who have been supported in their personal development” (Evans, 2021, p. 350).

Keeping in view the two analytical perspectives, this chapter explores the potential for fresh thinking on lifelong learning according to new realities in the interplay of the learning individual and the social organization of learning. Questions of how lifelong learning systems can recognize and support the learning of adults of all ages throughout, and beyond, extended working lives are central to international developments in the field and the possible answers vary according to the dominant discourse that is framing the debate at any particular time. Competing discourses co-exist, and the fact that one is more dominant at any time does not mean that the others have lost their power to explain or persuade.

A discourse that has been dominant in earlier times has taken as its point of departure that the exercise and preservation of democracy is of predominant importance in real life (we go to war in its name), that real life is about active and engaged citizenry, and the proper relationship between education and real life has to be understood in terms of lifelong engagement with the ideas and

practices of democracy. It is, for example, about educating ourselves collectively to exercise control over social impact and advances of technology. This version was important in western Europe in the early part of the 20th Century, at the time of the foundation of many civic universities and the international sweep of emancipatory discourses which are equal and opposite to the globalization discourses which are sweeping the world we inhabit a century on. If we take a different starting point for our analysis, in which the flowering of human potential is of predominant importance, then the logic of the learning individual begins to define the proper relationship between education and real life. *Learning to Be* (Fauré, 1972) defined the humanistic aim of “Lifelong Education” as “the fulfillment of man, through the flexible organization of different stages of education”, a process which should last the whole life for individuals (Fauré, 1972) and not just be tacked onto school or university for a privileged or specialized few. Husen (1974), in his well-known articulation of the concept of a learning society, emphasized not only “second chance” conceptions of lifelong learning but also the process by which untapped potential comes to be seen as the norm, not the exception, in the population. International bodies such as UNESCO used the humanistic version of lifelong learning to provide master concepts for educational planning, but their use represented worthy ideals with relatively little to show in the way of tangible advances in access to lifelong learning opportunities.

The global political consensus on lifelong learning which was constructed at the end of the 20 century was apparent in the Delors Report (Delors, 1996) the EU Competitiveness and Economic Growth Agenda and in statements of intent of OECD, the G8 countries and the Delhi Declaration. The EU Memorandum on Lifelong Learning, 2000 set out an agenda for lifelong learning for the first two decades of the 21st Century, based on analyses that emphasized the ways in which the nature of work and working lives are changing; the need to reform dysfunctional systems rooted in the norms of the past; the search for innovation, and “new skills for new jobs.”

Take up of the ideas of learning through the life-course as necessary to sustain livelihoods in times of critical social change fundamentally reshaped the discourses of lifelong learning. The basis for analysis of the “proper relationship between education and real life” came to be defined by the knowledge-driven economy, in which the relationship between education and “real life” is that “the more we learn, the more we earn.” We are engaged in a lifelong competition for livelihoods, learning for a living.

The role of government is recast as providing the means and encouragement for people to take responsibility for their own “employability,” as it is claimed that national governments can no longer guarantee employment in a global competitive environment, as governments seek to maximize their share of high skill high wage jobs in a global economy. The political consensus did not hold for long. The projections of OECD in 1997 showed growing awareness of the consequences of reducing learning, specifically lifelong learning, to investment in exploitable economic capital. Contrasts were drawn between the sense of control “over their own lives and their society” which comes from successful experience of education, with the isolation of the excluded. An equal investment in “social capital” was called for, but is the attempt to balance these two types of capital, social and economic, inherently contradictory? UNESCO, in an attempt to regain its role of values-based leadership in lifelong learning, has established the Global Monitoring of adult learning, with periodic Global Reports on Adult Learning and Education (GRALE, 2016, 2019) and international conferences to advance the Bélem Action Framework for adult education as a human right and as a means for transforming individuals, communities and societies as well as a means for economic development. According to UNESCO, although the perspective of economic development has been dominant, both the empowering and the instrumental rationales are needed in our societies (UNESCO, 2009a). Since then, lifelong learning has been incorporated in Sustainable Development Goals (SDGs), optimistically viewed as the beginning of a fourth generation in which lifelong learning is actively promoted in the context of international development (Elfert, 2019).

The analyses of governmental organizations and international agencies have concerned themselves principally with the social organization of institutions of learning, and the ways in which they need to be reorganized around new priorities to respond to social and economic changes. In this process the discontinuities of change are often exaggerated, while the continuities of disadvantage are under-estimated. New forms of learning are superimposed on old forms that nevertheless retain much of their original power. Social institutions, old and new, continue to interlock to shape typical life courses, that biographies that may still be typified according to social position. As Alheit and Dausien (2002) have argued, policies which aim to balance economic and social capital must take the “learning individual” much more seriously to avoid becoming trapped in the contradictions which lie at their heart. As well as continual reorganization of the institutions of learning, we need to try to understand better the reflexive ways in which people’s lives are shaped, bounded or change direction as they engage with these education, labor market and workplace institutions.

Much attention has been given to the impact of globalization and to the forms of modernization that are connected to globalizing tendencies. Yet modernization is neither uni-linear nor inevitable. There are strong differences rooted in local and national cultures which engage in different ways with globalizing influences.

The argument concerning the effects of globalization on education and training is that governments everywhere are conceding control to consumers and markets (leading to commodification of education). They are also being forced to concede control upwards to international organizations, and downwards to regional organizations. In this process, national education systems can start to lose their distinctive features as they begin to converge on a common instrumental norm. Social pluralism generates a growing diversity of needs which are met, increasingly, in privatized and individualistic ways. The logical conclusion is that it could eventually become impossible to transmit national cultures through education, as skill formation progressively displaces citizen formation as an educational goal, and “the collective project [of national education] is eclipsed by individualistic aspirations and norms” (Green, 1997, p. 4). Yet in moving from international discourses on lifelong learning to implementable policies at the national level, a view of learning as culture and lifestyle, a way of life, remains paramount in many societies (Fadzil, 2013).

European contexts for lifelong learning development

At least four models, analytically defined, can be identified in Europe. While all societies contain elements of all four models, it can be argued that one, or at most two, of the models have characterized, in broad terms, the context for lifelong learning development in any specific country.

The first model is characterized by strength of the “non-formal” sector. Where early school leaving generates inequalities in adult life, and aggregate skills levels and productivity levels are relatively low, the non-formal sector often plays an important role in supporting employment and families, potentially offering learning opportunities for young people and adults who have experienced barriers in formal settings of teaching and training. A strong culture of self-employment, especially in the countryside, will also often provide family support. Lifelong learning policies are directed toward mitigating problems of exclusion and disadvantage while putting in place supporting structures for adult learning that can ensure consistent access to learning opportunities and entitlements.

The second model is market-led, with learning arrangements that are close to labor markets, making work-integrated pathways possible. In such models, diversity in modes of schooling generates inequalities. Adult learning participation rates are often high, with measures designed to keep adults close to the changing labor markets and learning is often seen as ideally situated in the “real world” of work. Weaknesses include insecure pathways, in which private and public providers compete and initiatives come and go. New programmes and bridging schemes can be easily inserted into such a structure because it is so flexible. The flexibility also means that the pathways to be taken are insecure and, for those with the least advantages, the possibility of dropping out again remains a constant risk. In the market-driven structure the spread of incomes is large and tends to widen. This means that many become trapped in low-paid jobs, some of which require only minimal competences and provide little job satisfaction. Entitlements to wider forms of learning in adult life prioritize basic skills development.

“Dual” enterprise-school structures characterize the third model, built around secure structured education and training pathways that are associated with high aggregate skill and productivity. But inflexible pathways are associated with lower levels of participation in employment-related lifelong learning. The system does not easily allow for deviating pathways, which means that adults are constantly directed back to “square one” if they want to pursue a new occupational direction. High levels of participation in adult education build on traditions of supporting general education and integrating migrant populations.

The fourth model is characterized by the dominance of strong school-based structures. Egalitarian schooling, together with strong labor protection and regulation policies and redistributive effects from welfare systems, ensure relative income equality. High skills and productivity are further promoted through active labor market policies. High levels of participation in adult education build on a tradition of supporting general education. But barriers encountered by young people in making school-to-work transitions and weak education/industry links are often identified as impediments to effective implementation of lifelong learning policies. Educational “drop-out” becomes a problem under unfavorable conditions of the labor market, requiring the introduction of special initiatives to bring people back into the system in early adult life.

In practice most countries exhibit increasing hybridity in their approaches (Verdier, 2018). Societal trajectories are complex and even more so when abrupt changes have taken place whose ramifications take place over decades. This has applied most notably in the Eastern European and post-communist states in which multiple hybrids, built on organized markets and educational universalism, are being re-shaped through the interplay of internal socio-political logics and supra-national influences.

The interplay between international and national agendas for change

The key messages in lifelong learning policy espoused globally through international organizations (such as EU, UNESCO, OECD, ILO) emphasize over-arching priorities such as new basic skills for all, as primary skills for changing labor markets; increased investment in human resources; innovation, including shifts toward “user-oriented” or learner-centered learning systems; valuing learning, particularly recognizing informal and non-formal learning; the need for improved guidance and information for both young people and adults. Migrations of refugees have further highlighted the potential value of lifelong learning in recognizing previously acquired capabilities and integrating newcomers (Slowey and Schuetze, 2020).

In Europe, these international priorities have been interpreted and translated in EU lifelong learning policies in ways that place a strong accent on different forms of adults’ participation, political, social and economic.

Recent research on adult education (Kersh et al., 2021) compared country-specific approaches in policy development across Europe and neighboring countries. The research revealed both convergences and divergences in the development of adult education and lifelong learning policies and practices cross-nationally. Common trends in the provision of adult education that aims to foster different forms of participation and inclusion have been influenced by some common global challenges as well as EU policies and research in the area of adult education and lifelong learning. Specifically, policies and practices that aim to tackle social exclusion and promote social, political and economic participation of adults became centrally important to the European lifelong learning agenda. An economic rationale for lifelong learning as a means to secure and sustain livelihoods in times of critical social change has driven inclusion strategies focusing on employability and labor market skills. Tackling unemployment and equipping adults with the skills required by the contemporary labor market have been among most influential trends of lifelong learning, defining policy and practice responses across Europe and its neighboring countries. Strong interdependencies between economic, social and political forms of participation have also characterized some country-specific responses to contemporary challenges (Evans, 2009; Kersh et al., 2021). Policies and practices with a strong focus on the socio-economic dimension, that is, integration through entering

employment, promote versions of active citizenship implicitly rather than explicitly. According to this view, equipping adults with employability skills facilitates their chances to take a more active role in their social settings through their engagement with employment.

In practice governments everywhere pick and choose what to focus on and, more importantly, how to interpret concepts and priorities generated elsewhere, whether in the international literature or international organizations, in the context of their own systems, cultures and political stances. Governments implement measures that are consistent with their dominant socio-economic models and assumptions. For example, many Nordic interpretations see lifelong learning through a social welfare lens. Indeed, it was Nordic influences that secured a broadening of the initial [European Commission \(2000: 3\)](#) definition of Lifelong Learning (LLL) as “all purposeful learning activity undertaken on an ongoing basis with the aim of improving knowledge, skills and competence” to emphasize the range of perspectives, beyond employment, that can be taken on these activities: “all learning activity undertaken throughout life, with the aim of improving knowledge skills and competences within a personal, civic, social and/or employment-related perspective” ([European Commission, 2001](#), p. 33).

Moreover, the ways in which priorities are interpreted and acted upon in member (nation) states, depend crucially on relationships with existing forms of education and social provision. Socio-economic inclusion has also underpinned various education schemes set up by national governments, with the aim of integrating newcomers, such as refugees and migrants. However, as highlighted by Kersh et al.’s research ([2021](#)), the approaches toward inclusion are often driven by national political priorities rather than by the multiple needs of adults, specifically those, in vulnerable situations.

Relationships with existing traditions of adult education are always an issue, as attention has focused progressively, at level of international organizations, on how the outcomes of “informal” lifelong learning can be better recognized and certified to support adults across lengthening (working) lives and shift educational systems toward lifelong learning objectives.

“Informal learning” recognition is pivotal for lifelong learning strategies

Informal learning has been described as not organized, unintentional, and is often referred to as “learning by experience” or simply as “experience” ([OECD, 2010](#), p. 22). It relates to the capabilities that people can learn from a range of experiences, such as education, workplace activities and learning, family experience, community work ([Eraut, 2004](#)). The approaches toward conceptualizing informal learning (and informal skills) have been commonly based on the contention that significant capabilities have been acquired as a result of prior learning and, more generally, prior experiences. The development of knowledge and skill is often tacit in nature and thus individuals do not necessarily recognize to what extent they use their previously acquired skills in their current practices or draw on their previously acquired knowledge ([Evans, Kersh, and Sakamoto, 2004](#)). The benefits of capturing such skills for the purpose of recognition and accreditation have been recognized as significant measures of progress for different kinds of learners, including those who find themselves in vulnerable positions, such as refugees and migrants. As [Hart and Chakroun \(2019, p. 13\)](#) put it “the volume of migration has created a need for mechanisms and agreements to assist both those making claims for recognition and those responding to these claims by giving employment or granting admission to further learning” (2019, p. 13). Recognition of learning outcomes irrespective of how and where they originate thus potentially contributes to fostering equity and strengthening access to education and to the labor market for various disadvantaged groups, including young people and older learners ([OECD, 2010](#)).

The strategic processes by which lifelong learning can be promoted at international level, for take up in widely differing systems and cultures, are most comprehensively exemplified by the European Union development process. Validation (accreditation) of forms of learning characterized as informal and non-formal became cornerstones to plans for overcoming barriers and resistances to the realization of adequate lifelong learning systems across Europe. The 1995 Commission *White Paper on Teaching and Learning* ([European Commission, 1995](#); [Dukekot et al., 2005](#)) is often cited as a formative paper in the development of policies to promote validation of learning outside and beyond formal systems at the European level. Another influential document, the 2001 Communication of the European Commission: *Making the European area of lifelong learning a reality* ([European Commission, 2001](#)) further emphasized the significance of validation of informal learning as well as recognition of learning through the life course. This policy development was strongly supported by the 2002 Copenhagen declaration, which defined the European strategy for enhanced cooperation in vocational education and training ([European Council and European Commission, 2002](#)). Subsequently, many lifelong learning policies and initiatives have been characterized by their focus on validation of “informal learning” and accreditation of outcomes of learning irrespective of where and how that learning has occurred. As noted by [Villalba and Bjørnåvold \(2017\)](#) various European programmes (e.g. Leonardo da Vinci, Grundtvig and Socrates) played a key role in testing solutions and disseminating experiences of validation and further supporting the setting up of validation arrangements in various European countries.

At national level, policies on validation and accreditation have exhibited both some common and diverging trends in setting out and implementing these initiatives. The 2008 adoption of the European qualifications framework (EQF) has been highlighted as one of key developments, facilitating the process of validation across European countries. As observed by [Villalba and Bjørnåvold \(2017, p. 75\)](#) “the long-term effect of this, directly influencing validation, is the more systematic promotion of learning outcomes at national level.” Following this, The European Council 2012 Recommendation on validation of non-formal and informal learning ([Council of the European Union, 2012](#)) has become an important landmark in the development of policies and practices of validation of non-formal and informal learning in Europe. The recommendation stressed the importance of “offering individuals the opportunity to demonstrate what they have learned outside formal education,” where recognition of prior learning means the

validation of learning outcomes, "whether from formal education or non-formal or informal learning, acquired before requesting validation" (Council of the European Union, 2012). Within this broad interpretation, European countries have translated and adapted this concept to their specific contexts. Although the specific features of the process of validation of informal and prior learning vary between different country contexts and the extent to which they have been grafted onto existing approaches and long-standing cultural commitments, some common broad principles have been identified. As summarized by Villalba-Garcia (2019, pp. 45–46) the processes of validation of informal/non-formal learning across different countries, share the features that they are voluntary processes based on the identification of learning outcomes irrespective of how and where the occurred. Their validation can lead to different types of qualification, distinguished according to criteria of demonstrated knowledge, skill, attitudes and competence.

The many classifications of approaches reveal multiple dimensions of variation. The topology developed by Damesin et al. (2014) focuses on the interplay between public learning validation policies and the mode of involvement of the social players, specifically identifying countries where validation of learning, irrespective of how and where the individual has learned, are integral to development of lifelong learning system (Denmark, Finland, France and Portugal); countries where validation of learning outside formal systems is primarily a matter for local and regional initiatives, and targets particular sectors and/or professions (Italy, Spain) countries where more or less active trade union intervention in terms of training goes hand in hand with an incomplete institutional system for validation of learning outside formal systems, whose development is not considered to be a priority: Germany, Romania and Poland.

Examples of ways in which international defined priorities and policy drivers play out at national and local levels illustrate how path dependencies generate contrasting results "on the ground," often reinforcing structural inequalities. The discussion so far yields insights that are in some respects specific to variations in the European context and in other respects resonate with experiences captured in global reports of UNESCO, ILO. The Global Report on Adult Learning and Education (GRALE 4) report (GRALE, 2019) has compiled evidence of the persistence of deep-rooted inequalities in participation in adult learning and education, and calls for major changes in approach, backed by adequate investment, in the context of the Sustainable Development Goals.

As alternative approaches and structures become embedded and institutionalized, quality frameworks have become important for their long-term sustainability. The international organizations have sought to promote transparency and to create the conditions for co-operation and exchange across borders, in recognition of diversity and changing landscapes at national and local levels (EU Renewed agenda for lifelong learning 2012–2014). EU priorities have a labor market and stakeholder orientation, contrasting with that of the UNESCO (2010, p. 8) Bélem framework which emphasizes the need to "foster a culture of quality in adult learning" including the enrichment of learning environments, motivation and empowerment of individuals and communities and the role of public authorities in ensuring effectiveness and the rights of users of services.

Analytic perspectives and theoretical approaches question dominant discourse

Beyond, and independently from, the concerted efforts of international organizations to overcome obstacles to systemic development of lifelong learning by concrete means, the two analytic perspectives—on the social organization of learning and the learning individual, respectively—reveal the fundamental need for much more inclusive accounting of the capabilities of adults and the circumstances in which learning arises, across and beyond extended working lives.

These analytic perspectives can be considered in tandem with two broad avenues for inquiry into lifelong learning and human development. The first theoretical approach focuses on the individual knowledge and skills that are part of human capital, and on learning and development as human capital accumulation. The second theoretical approach sees human capabilities as shaped by context and social practices. These lenses focus attention, in different ways, in which the learning and development is both embedded in and stimulated by personal and work situations in adult life. In four quadrants, Fig. 1 outlines the assumptions and beliefs in these different analytic perspectives from the perspective of an individual focus on learning and a social perspective on learning.

Human capital development that focuses on the learning individual

In the context of lifelong learning this perspective translates into policy arguments which assume that developing competences will bring the greater likelihood for an economically sustainable life. In this view, the absence of competences portrayed as key, core or foundational, can impact negatively on an individual's economic and social opportunities. Inquiries into the efficacy of lifelong learning have to track individual journeys over time to demonstrate sustainability of working life and they also have to address the complexity of the relationship between adult learning and adult experiences (Reder and Bynner, 2009).

Human capital development that focuses on the social organization of learning

Although most of the literature on human capital examines the relationship between individual human capital and individual earnings and life-experiences, human capital development is recognized as having broader social dimensions in health, welfare, social participation and poverty reduction (McMahon and Oketch, 2013). It is argued that higher levels of human capital have spill-over effects. In other words, a society with large numbers of educated and skilled people is believed to benefit in ways which go beyond

	Human capital approaches	Social process approaches
Focus on the learning individual	A Learning clearly defined sets of skills and competences, the absence of which can impact negatively on an individual's economic and social opportunities.	B Emphasises socially positioned life course and biographical narrative; embedded and embodied learning.
Focus on social organisation of learning	C Emphasises shaping and organising education and adult learning 'provision' for socio-economic ends such as increased productivity, social mobility.	D Emphasises environments and affordances for learning; communities of social practice; informal and 'everyday' learning.

Fig. 1 Broad avenues for inquiry into lifelong learning and human development. Adapted from [Evans \(2011\)](#).

the higher incomes and better life-chances of the skilled individuals themselves. The people who work alongside skilled people will also be more productive, and there will organization-wide changes which would not occur without the presence of skilled individuals. This insight applies across all forms of organization from the company to the voluntary organization, from the firm to the local community group, orchestra, choir or athletics club. Conversely the spiraling down of skills and abilities in successive low-quality assignments may also have negative spillover effects, as yet unresearched.

Learning as social process that focuses on the learning individual

In this perspective learning journeys in adult life are defined in terms of biography and socially embedded learning, recognizing that adult learning takes on a genuinely active, unpredictable quality when it draws on resources in "borderless" ways, in critical life situations and turning points in the life-course ([Chisholm, 2008](#); [Biasin and Evans, 2019](#)). Furthermore, people's beliefs in their ability to change their situation by their own efforts, individually or collectively, are significant for the development of their capabilities. These beliefs change and develop over time and according to life experiences. Notions of borderlessness view learning as becoming more extensive (lifelong), more specialized (life-near), more differentiated (life-wide), more flexible, more individualized and more contingent ([Chisholm 2008:142](#)).

Learning as social practice, focusing on the social organization of learning

Learning as a social practice emphasizes the social context of knowledge and capabilities that are learnt and developed over time, with attention to important milieus for development of capabilities and immersion in cultures. Situated learning theories enrich the concept of learning space; emphasizing socialization into a wider community of practice that involves membership, identity formation and expertise development through participation in the activities of social practices ([Lave and Wenger, 1991](#); [Kersh, 2015](#)). In this view the group is seen as important rather than the individual, and people learn through shared practices of the community, with individuals actively influencing one another's learning and enculturation through a process of co-participation ([Billett, 2004](#)). Learning thus becomes the expansion of human capabilities through the lived experiences and social relations of activity.

Researching the learning and development of adults takes each of these analytic and theoretical perspectives to the limits of explanatory and exploratory power. New conceptual approaches are showing how adult learning and the exercise of contextualized preferences in adult life involve much more than a series of rational choice calculations ([Evans et al., 2013](#); [Evans, 2021](#)), while cultural signs and tools such as "qualifications" and "standards" ([Wertsch 1998](#)) mediate conceptualization of skills, intelligence and capability and what people believe is possible for them and for others to achieve.

As argued previously, recognizing and certifying individuals who have demonstrable capabilities but are not in possession of the official forms of recognition that are needed for them to practice or progress has been a longstanding priority in the development of lifelong learning systems. The search for workable mechanisms that can connect the learning individual with the social organization of learning has been driven internationally by the need for concrete instruments that can translate lifelong learning principles into action. The definition and recognition of "non-formal and informal learning" have been central to the process.

To function effectively, new approaches to recognizing and certifying learning and the concepts, cultural signs and tools associated with them have to become embedded in the wider eco-systems of opportunities. Of course, concepts and associated mechanisms for recognizing and certifying adult learning already existed in different forms in the dominant model(s) outlined above

and, in many cases, fundamental questions have been generated as approaches reliant on definitions of informal and non-formal learning and driven by the international organization priorities entered the field and started to change the rules of the game. Multiple contextual and cultural factors come into play, as the comparisons of the next section reveal.

Reframing debate and action beyond “formal, non-formal or informal” learning

The debates about formal, informal and non-formal learning which have structured development at the international level, are connected in complicated ways with conceptual understandings of adult learning and also with culturally embedded educational development at national and local levels. A team of scholars (Harring et al., 2016) set out to explore different understandings and approaches internationally, considering variations in context and concept as well as implementation efforts through cases exemplifying the diversity of Asian approaches (focusing on Japan and Bangladesh) and North American perspectives (from US and Canada), as well as variations in Europe. The results reveal not only contextual variations but are also indicative of social-ecological interdependencies of learning and practice.

There is no Japanese language term to distinguish informal learning from non-formal and formal education, although the idea of learning throughout life and from all experiences is culturally embedded. Informal learning was imported as a foreign term into the educational lexicon from the late 1970s, as a precursor to the Japanese Government’s phased implementation, from the late 1980s, of policy measures to construct a lifelong learning society. The policy process adopted UNESCO definitions incorporating informal learning as the unintentional learning of knowledge skills attitudes and perspectives occurring in family, community and workplace spaces as well as through multi-media and the internet (Sawano, 2015).

In the contrasting Asian context of Bangladesh, Shohel (2015) has also observed that there was no place for acknowledging informal learning in mainstream education, a scenario that international organizations have explicitly challenged in the promotion of lifelong learning systems. Informal, non-formal and formal learning are portrayed holistically as “three types of currents flowing in same ocean of education – overlapping and very hard to separate” (Shohel, 2015, p. 277). When learning is viewed as a holistic process, elders, parents, employers and peers are seen to help individuals in analyzing incidental everyday experiences in ways that can make tacit knowledge explicit, with entertainment, gossip and chats, fables and storytelling, indigenous knowledge transfer, religious congregation all identified in a rich cultural appreciation of the scope and nature of learning beyond schooling.

Japan and Bangladesh, despite their obvious socio-economic and political differences, have thus both adopted terminologies from international organizations for policy purposes. These terminologies have been superimposed, in both examples, on culturally embedded and pervasive notions of the lifelong importance of unintentional forms of learning.

North American contributions trace a shift in thinking toward more elaborated understandings of the nature of adult learning (Watkins and Marsick, 2015), moving on from preoccupations with place and setting to an increasing focus on the open-ended, collaborative, social and contextually dependent learning that evolves and transforms over time and adapts according to resources and technology. From a Swedish perspective, Norqvist et al. (2015) have embraced a plurality of approaches, arguing that this is the last generation to experience a clear definition of when learning is “school” or is “not school.” In an age of online and digital learning, it is important to ask whether and to whom these distinctions matter in life worlds of the learning individual; Norqvist et al. (2015) advance the case for an integrative view of learning in a digital media world, based on the notion of pedagogical attitude. Further to this, (Singh, 2015), p. 20) has argued that learning must not be seen as “dichotomous and discrete categories, but rather as continuous elements within the ‘learning continuum’.” Less attention to formal/informal definitional debates and more to the combination and interplay of the “currents” of learning, potentially advances deeper insights into the multiple ways in which systems of representation are built up in ways which govern modes of thinking and acting in the world.

The definitional debate about formal, non-formal and informal learning is arguably becoming redundant. The definitions have been comprehensively used to challenge dominant assumptions that equated worthwhile learning with formal education. They have been used to erode “artificial and outmoded barriers” (Faure, 1972, p. 189) and have, in that respect, been fundamental to the mission of international organizations to create conditions more conducive to the development of lifelong learning systems. This process has often been linked, in a rather generalized way, with neo-liberal reforms.

The development of the French system provides a counter example to prevailing assumptions that systems for recognition at national levels are unequivocally driven and shaped by neo-liberal reform agendas. Lessons from the French model are of considerable interest at the present time, since they represent successful introduction of the validation of experiential learning outcomes into a national context and culture of relative academic elitism. To remedy perceived “social justice deficit” and weakness in equality of opportunity, legislation in 2002 established the right for all working individuals to earn a recognized diploma or professional qualification through the accreditation of prior experience. According to Rémy and Merle (2014) the implementation of APL can now be seen as a “small revolution” in France. The 2002 Validation of Acquired Experiences (VAE) allowed “informal routes to qualifications that are formal,” assessed against officially recognized standards used throughout the educational systems. The concept of informal learning had little currency in France and was not influential in this VAE development, according to Werquin (2015) who argues that it is rooted in 200 year-old commitments to the principle that for workers to be productive and to remain so they have to be trained throughout life. While there is body of literature on learning that is not formal, it is “relatively scarce” (Werquin 2015, p. 185) compared to an extensive literature on experience, experiential learning and “*acquis d’apprentissage*” which is distinctively French in origin and has been pioneering in approach. Moreover, the concepts of informal, non-formal and formal learning are most often used to by international organizations rather than researchers, leading Werquin to comment that these are not

airtight categories and to observe that only institutions that have an immediate interest in using the concepts for concrete actions are involved in promoting the definitions.

The VAE system targets the less qualified yet competent adults, aiming to make visible the learning outcomes that they have achieved through any type of activities that involve learning and that they can demonstrate in practice. The VAE system requires preparation of two portfolios: one portfolio to support candidature by establishing eligibility; the second portfolio for the main assessment, against criteria, by a panel. Accrediting institutions have to set out how candidates should demonstrate skills and knowledge, how they should be guided in building solid “candidature” and how juries will be chosen to assess. This removes barriers to candidates accessing institutions and comes to rely on how adults can gain the quality of experiences. The candidates are assessed by interview and practical tests. The candidates prepare their narratives with guidance, analyzing and selecting from their work history and informally acquired knowledge which might have been gained through community activities, experience in other cultures, the pursuit of personal interests or other means. The challenges that face the system, which has substantially increased take up since it started in 2002, are securing parity of esteem for adults who have taken this route. Even though they have achieved exactly the same qualification and standards as those who have qualified through the conventional routes there is, nevertheless, an enduring, culturally embedded lack of belief in “true” equivalence of alternatives to conventional modes that resonates in many other contexts. Many people who are already qualified add to their qualifications through this system, but the fact that half of all beneficiaries have been at the first level of the French NQF indicates success in reaching previously unqualified adults. The qualification they gain has dual currency—both for further progression to the next level of education and in securing positions in the labor force.

The example of France has been chosen here as it contains insights for systems and societies seeking means and modes for supporting and recognizing adult learning at a national level. The system provides an incomplete solution that works partially for a proportion of adults. It is both instrumental and empowering, within its own limits. It is home grown, neither neo-liberal in conception nor universal in its applicability. It is both enabled and limited by the its embeddedness in tradition and is set to evolve in the context of changing ecologies of learning and practice.

Beyond working life applications, it is important to note that the broader recognition of adult learning includes action to promote environments and learning spaces which are rich in opportunities. Public non-profit cultural spaces may not have overt educational purposes—but have powerful effects on the cultural languages of life and people’s understandings of themselves in the world (Halttunen, Koivisto, and Billett, 2014).

Pedagogies centered on fresh understanding of how and why adults learn (Carré, 2020; Norqvist et al., 2015) can enhance the ways adults make meaning and are activated in changing social landscapes. They are part of the ecologies of learning and practice (Barnett and Jackson, 2020) that are interdependent not only with technological developments but also with local responses to global issues such as inequality, migration, climate change and pandemic responses.

Conclusions

The search for ways of recognizing the learning of adults beyond initial schooling lies at the heart of lifelong learning and its long-term evolution as the organizing concept for education systems of the future. The definitional debate about formal, non-formal, and informal learning has probably served its purposes, challenging dominant assumptions that equated worthwhile learning with formal education. The concepts became central to the efforts of international organizations to create conditions more conducive to the development of lifelong learning systems. They have endured for this reason but are superseded, we argue, both conceptually and in a context in which upcoming generations are unlikely to equate learning with formal education in the way of previous generations and will not make the same assumptions about how, why and where people learn.

In the modern world, ideas for better connecting system worlds and the life-worlds of learning individuals can now focus compellingly on learning as a lifelong process which links rather than separates generations. Adults moving in changing social landscapes have strivings, aspirations and scope for action to change lives for the better, individually and collectively. An holistic, triadic vision for lifelong learning that calls for people to look for new options beyond the choices laid before them also has to recognize that human development is profoundly affected by macro-economic conditions, institutional structures, social background, gender and ethnicity as well as acquired attributes and resources available through family, communities networks. Bringing the lifelong perspective of the learning individual more centrally into debates about the social organization of education and learning means recognizing changing ecologies of learning and social practice and rethinking connections between system worlds and life worlds, over time. This process also highlights the challenges for triadic conceptions of lifelong learning in supporting the development of educated attributes, abilities to read the world critically and protecting environments that enable young people and adults to learn mutual responsibility in the collective free spaces of life.

Introduction

In this article, the focus is on conceptualization and theorization of transitions as there is a clear gap in literature about these (Jindal-Snape et al., 2020, 2021). Given that these form the very basis of good research, policy and practice, it is important to start a debate and discussion about transitions based on our 15 years plus transitions research across educational stages and life course. As educational transitions do not happen in a vacuum and are accompanied by, or trigger and are triggered by, other transitions, it is important to understand them as multiple transitions. For example, a student moving to higher education would experience a transition related to academic level of studies, relationship transitions such as leaving existing friends and creating new friendships, geographical transitions such as moving to a new city, developmental transitions and accompanying identity transitions from a young person to a young adult, living independently, to name but a few (Jindal-Snape and Rienties, 2016). Therefore, in the following sections we will consider educational transitions in the context of all these multiple transitions. The article starts with the conceptualization of transitions, followed by defining successful transitions, and theoretical frameworks used in transitions research. The educational stages and sectors covered include primary and secondary schools, transitions to and through university (international students, students identifying as LGBTQ+, and those with life limiting health conditions), and continuing professional development of higher stage medical trainees. At the end, some new concepts have been introduced and provide an insight into how successful transitions can be facilitated.

Conceptualization of transitions

Transitions can be defined as an ongoing process of psychological, social and educational adaptations due to changes in context, interpersonal relationships and/or identity, which can be simultaneously exciting and worrying for an individual and others in their lives, and which can require ongoing additional support (Jindal-Snape, 2016, 2018). The theories underpinning this conceptualization are Multiple and Multi-dimensional Transitions Theory (MMT Theory, Jindal-Snape, 2016), and Educational and Life Transitions Theory (ELT Theory, Jindal-Snape, 2016; Jindal-Snape and Ingram, 2013) which will be discussed later.

However, if you consider transitions literature, it is clear that there is no shared understanding among researchers, professionals and policy makers about the definition of transitions (Jindal-Snape et al., 2020). The way that researchers conceptualize educational and life transitions has important implications for their research designs, study findings and their interpretation, and implications emerging from that which are used to inform future research, policy and practice.

This view of the lack of conceptualization, in part, is based on a recent systematic literature review of primary-secondary transitions research articles written between 2008 and 2018. Most authors of the 96 articles included in the review had not clearly defined or operationalized transitions (Jindal-Snape et al., 2020, 2021). A team of four researchers had to establish their conceptualization through inferring from either words they had used, any theory they had cited or their methodology; there were multiple conceptualizations in some articles for that reason; a rigorous cross-check was undertaken to avoid inaccuracies in categorization. A total of 54 papers seemed to consider transition to be change with a focus on changes in pedagogical approach (e.g., Mackenzie et al., 2012), organization (e.g., Arens et al., 2013) or systems (e.g., Strnadova et al., 2016). This seems to be similar to health

education literature, in which authors have conceptualized transitions as change, for instance, in daily routines and social networks (Draus et al., 2014). Forty one papers conceptualized primary-secondary transitions as a normative life transition, within which 13 articles presented it as a normative life event (Neal et al., 2016); 20 articles conceptualized it as a normative period in educational journey (e.g., Brewin and Statham, 2011; Burchinal et al., 2008; Weiss and Baker-Smith, 2010); 11 papers referred to multiple transitions with multiple changes being experienced at the same time (e.g., Knesting et al., 2008; Lofgran et al., 2015; Serbin et al., 2013). Eight articles referred to transition as disruptive and highlighted the risk factors for children (Keay et al., 2015; Mackenzie et al., 2012; Maher and Maher, 2010), with six highlighting it as a time of curricular and relational discontinuity (e.g., Makin and Pellicano, 2017; Rainer and Cropley, 2015). The latter could be seen to be similar to the conceptualization of transition as change. Three articles used a life course conceptualization (Benner and Wang, 2014; Fortuna, 2014; Witherspoon and Ennett, 2011), three a rite of passage (Bailey and Baines, 2012; Rainer and Cropley, 2015; West et al., 2010), and three conceptualized it as a turning point (Andreas and Jackson, 2015; Langenkamp, 2010; Scanlon et al., 2016).

From most studies it is not clear whether the authors asked their participants about their conceptualization of transitions (Jindal-Snape et al., 2020). In one study, also in the context of primary-secondary transitions, professionals were asked about their conceptualization and it was found that they did not have a shared understanding within the same school or group of schools, with conceptualization ranging from “change” to “adaptation to change” (Jindal-Snape and Cantali, 2019). In another longitudinal study, the participants, who were higher stage medical trainees, were asked what transitions meant to them, and notably their views changed over time from transitions being about a change and being singular (at the start of the study), to a more complex, dynamic and multiple process (after 6–9 months).

Another interesting aspect that emerged from studying conceptualizations in existing primary-secondary transitions literature (Jindal-Snape et al., 2020) is that the discourse around transitions is primarily negative (60/96 articles; e.g., McIntosh et al., 2008; Mudaly and Sukhdeo, 2015; Peters and Brooks, 2016; Poorthuis et al., 2014; Serbin et al., 2013; Tso and Strnadova, 2017; Vasquez-Salgado and Chavira, 2014), with 25 that had a mixed discourse (but 15 more negative than positive), nine neutral and only two predominantly positive (Madjar and Chohat, 2017; Neal and Frederickson, 2016).

The articles with a negative or mixed discourse had used previous literature in their introduction to provide the context of transitions and their findings matched the previous literature. It is not clear whether the purpose of undertaking these studies was due to difficulties that had been noticed in schools and schools inviting researchers to undertake the study, leading to a negative discourse or whether the researchers’ thinking had been informed by prior research and had designed the study and questions in a way that they elicited primarily negative transition experiences. Interestingly, most authors had published a one-off study about transitions and therefore it was not possible to see any trends, including change, in the authors’ conceptualizations over the years. Further, it is possible that they had therefore relied on previous authors’ conceptualizations of transitions which had not been clearly articulated and/or used a primarily negative discourse.

This is concerning as the negative discourse in research literature might influence the views of professionals, families and learners, to the extent that they might anticipate a negative experience leading to unnecessary anxiety till they experience the reality of transitions, that might not be negative, over the life course. This is also set in the context of the societal environment where adults and family members (Jindal-Snape and Foggie, 2008) and popular media, such as story books, novels and movies also depict transitions as problematic with bullying from peers, stricter teachers, massive difference in academic level etc. However, in practice, educational transitions are in the main positive. For instance, transitions to higher education, especially for international students, is a result of hard work at school, opportunity to study in their chosen discipline, with international academics and being successful in getting prestigious and competitive scholarship (Jindal-Snape and Rienties, 2016). Therefore, it is important that the discourse is balanced and researchers investigate both, positive and negative, transition experiences (e.g., see Jindal-Snape and Cantali, 2019).

Another aspect worth considering is that the research designs that were used in the articles reviewed by Jindal-Snape et al. (2020), most had collected data just before and after the move to secondary school, capturing the immediate perceptions of children without considering their adaptation over time. This was also the case in healthcare literature as suggested by a literature review of 23 studies published between 1994 and 2004, with only one study using a longitudinal design and the rest focusing on a specific event in a short time frame (Kralik et al., 2006). From our four stage longitudinal study (final year of primary school to end of second year of secondary school), it was clear that different children adapted to change at different times and that their transitions were dynamic and multiple with different transition experiences at the same time (Jindal-Snape and Cantali, 2019).

Similarly, the way professionals and policy makers conceptualize transitions has a major impact on transitions practices. For instance, if transition is conceptualized as a one-off significant event such as starting secondary school, the transitions support is likely to be provided just before and/or after the move to secondary school. This can be highly problematic as we found in our four-stage study which collected data from students in the final year of primary school, and twice in the first year and once in the second year of secondary school (Jindal-Snape and Cantali, 2019). As mentioned earlier, we found that transitions were ongoing and dynamic, and the student participants reported that what they were excited about when in primary school continued to be good in secondary school. However, the concerns they had in primary school declined over time. More importantly, we found that a number of students experienced some problems at the start but adapted later; whereas for some students, problems emerged at the end of the first and at the start of the second year of secondary school with no transitions support available to them, apart from some students reporting that guidance staff were available to anyone experiencing any problems. This can be explained to some extent by the conceptualization of professionals in this primary-secondary school group. There was a lack of shared understanding about what transitions mean, with some conceptualizing them as a one-off event linked with major moves at particular

stages and time points, while others as an ongoing process of multiple changes, such as changes in the physical and social environment at school, with limited attention to adaptation over time (Jindal-Snape, 2018; Jindal-Snape and Cantali, 2019).

Defining successful transitions

Similar to the lack of clear definition of transitions, the term successful transitions is used without defining it, with the focus being on a dip in attainment and/or self-esteem.

In an educational context, there has been an emphasis on academic adjustment. A student was seen to have adjusted well if they had good attainment, engagement at school/university and regular attendance (e.g., Rice et al., n.d.). However, there has been some shift with a recognition that social and emotional adjustment at school/university are equally important, if not more so. These include connectedness and sense of belonging with the organization, and development of positive and mutually respectful relationships (Jindal-Snape and Rienties, 2016; Peters, 2010; Rice et al., n.d.).

Further, it is important to be mindful of the fact that successful transitions might mean something totally different, depending on whom we ask. For instance, from the perspective of the healthcare staff in Kirby et al. (2014) study on transitions to palliative care, successful transitions were seen to be an acceptance of medical futility on the part of the patient, pain and symptom management, and wellbeing of patient and family psychologically. The patients and families might have had a different perspective to this.

In Evangelou et al. (2008) study in an English primary-secondary school context, the professionals suggested that the indicators of successful transition was timely actioning of parental choices, children getting admission to their school of choice and reduction in placement appeals. However, children and parents reported that successful transitions meant making new friends, no concerns about settling in school, increase in engagement at the new school, adapting to the school routines, enhanced self-esteem and confidence, and curricular continuity.

In another study, for instance, at the time of the first interviews, two children reported being bullied after moving to the secondary school, which was having a very negative impact on their wellbeing (Jindal-Snape and Foggie, 2008). In the subsequent stage, one child reported that they had carried on but with similar issues whereas the other child and parent decided to leave that school to access an alternative curriculum where the child was happier. The question it raises is, which child was experiencing a successful transition? And who decides who is having a successful transition or not? Therefore, it is important that the person who is most affected by transitions is asked what successful transition for them might be.

Theoretical perspectives

The most prevalent theories in literature that have been used to explain any aspect of transitions have been Stage-Environment Fit Theory (Eccles and Midgley, 1989; Eccles et al., 1993), Bronfenbrenner's Ecological Systems Theory (1993), Life Course Theory (Elder, 1998), Self-determination Theory (Ryan and Deci, 2000), Resilience (Luthar, 2006; Newman and Blackburn, 2002 linked it with transitions; Rutter, 1987), Emotional Intelligence (Goleman, 1995) and Self-esteem (Mruk, 1999; Jindal-Snape and Miller, 2008 linked self-esteem and resilience with transitions). Usually these theories are referred to in the introduction of an article but there is little evidence of the theories feeding into the conceptualization, research design and/or being used to explain the results. Apart from the Life Course Theory, none of the other theories, explicitly refers to transitions. Despite this, none of the articles critiqued the theory/ies and, more importantly, they did not suggest any further development of these theories based on their research context, nor did they develop new transitions theory/ies.

Adapting theories borrowed from other contexts and disciplines

When considering the transitions of international students, initial research literature in the field focused on existing *acculturation* theories which were based on the transition experiences of migrants who were seen to be experiencing culture shock. Culture shock is based on the premise that when a person experiences a new culture, the difference between their own culture and that of the host country, will lead to the migrant experiencing stress and shock. Three groups of theories were used to explain acculturation: Stress and coping (Affect) theories which hypothesize that life changes are bound to be stressful and a migrant needs to develop coping strategies to help combat stress; Culture learning (Behavior) theories that highlighted that social interaction is important for migrants and that they need to learn culturally appropriate social skills to survive in the new culture and context; and Social identification (Cognitive) theories that hypothesize that any cross-cultural transition will lead to a change in cultural identity. This ABC of acculturation theoretical framework (Ward et al., 2001) offered a better understanding of the multi-dimensional processes involved in the acculturation of migrants.

However, all these theories seemed to consider the migrant and, in our context, the international student, as passive. This changed as Berry (2005) moved the thinking and suggested that migrants' attitudes toward acculturation and strategies used could lead to four outcomes, namely, integration (maintains original identity and accepts new culture), assimilation (rejects original and accepts host identity), separation (only identifies with original culture), and marginalization (rejection of both cultural identities) (Fig. 1). Choice in this context is important but integration is seen to be the healthiest acculturation strategy. He also discussed the

Fig. 1 Acculturation strategies. Based on [Berry \(1997\)](#).

mutual nature of acculturation, that is, it is bi-dimensional rather than uni-dimensional ([Berry, 2005, 2006; Smith and Khawaja, 2011](#)).

However, there is, potentially, an issue in applying theories, developed in the context of economic migrants, to international students' transitions. International students have a different motivation to study abroad; they are seen to be top level students, bringing with them large funding as fees, helping economic regeneration due to increased spending in the host nation, and are seen to enrich the host university's academic environment. They carefully choose the country and university they would like to move to and these decisions are made based on the best match with their aspirations and needs. Their main purpose when studying abroad is to integrate in the host environment.

Taking conceptualizations of migrants' transitions further, both the international student and the host university and community experience acculturation and there is mutual adaptation with strong emphasis on mutual connectedness. This moves the ABC theory further to a social, Ecological Systems Theory perspective ([Bronfenbrenner, 1979](#)), highlighting the role of the wider society in the acculturation of international students ([Bethel et al., 2016](#)). This change in the theoretical framework emphasizes that the international students are not passive and actively adapt to the differences in cultural and pedagogical approaches of the host nation. This was also apparent in an educational context; [Zhou et al. \(2008\)](#) found that UK higher education staff adapted their teaching style and assessment practices to accommodate international students' pedagogical needs. One could argue that these acculturation processes and attitudes are, in some ways, similar to pedagogical attitudes although they can be dictated, to a large extent, by assessment practices of the host nation and university. This has led to increasing calls for internationalization of curriculum, although few have raised voice about internationalization of pedagogical approaches.

However, it was important to consider how these theories could be applied to transitions of international students and whether they were fit for purpose. This led to the development of a theoretical framework called Social Network-Affective, Behavior and Cognition (SN-ABC) ([Rienties and Jindal-Snape, 2016a,b](#); see [Fig. 2](#)), pulling together ABCs of acculturation, Social Network theories and Social Capital Theory ([Putnam, 2001; Rienties et al., 2015](#)) by undertaking research in international classrooms.

Unlike previous theories used to understand international students' transitions, SN-ABC is based on the belief that students do not passively experience "culture shock" or "pedagogical shock", and that they proactively choose to behave in particular ways for adaptation to the cultural and pedagogical environment in the host country; admittedly sometimes these decisions might not be consciously made by the student ([Rienties and Jindal-Snape, 2016a,b; Rienties et al., 2015](#)). Further, the environment, whether human, physical or social, in which these interactions and transitions take place, plays a substantial role in the outcomes, as there will be an impact of the university and/or national policy, educational practices and assessments, and the local community on all students. Therefore, although the student characteristics and motivation to interact and adapt (see [Fig. 1](#)) might act as mediating factors, simple modifications of the environment could have an impact on the international students and the host context, such as hosting of students by community members for a weekend, assessments that involve small group work that require host and international students to work together, as well as community organizations and universities providing support to their family if they travel with them. This is an important example of understanding the limitations of using previous theories and the need to

Fig. 2 SN-ABC theory. From Rienties and Jindal-Snape (2016a,b).

adapt them for one's particular context. Further, this shows how a new theory, that is fit-for-purpose for transitions research, policy and practice, can be developed.

Developing research informed transitions theories

Educational and life transitions (ELT) theory

Based on research with international doctoral students, an Educational and Life Transitions (ELT) theory was proposed (Jindal-Snape and Ingram, 2013) as it was found that not only did they experience educational transitions due to, for example, change in academic level, academic protocols, assessment styles but they also experienced other life transitions due to, for example, moving to a new country with different social and cultural norms, leaving or bringing family members with them and financial aspects. And that these transitions were dynamic and happened at the same time, with the possibility of one transition experience being positive and another being negative. Further, these different experiences interacted with each other. If the positive transition experiences were stronger than the negative experiences, they could act as a buffer; for example, if the academic transitions are going well, they could mitigate the negative peer relationship transitions (see Fig. 3). However, if the overall negative transitions experiences are overpowering, the positive transition experiences might be overlooked; for example, an international student struggling financially might find it so overwhelming that any success in their studies might not lead to any positive experiences.

It is also important to remember that the multiple transitions are dynamic and the student might have different experiences at different times. Further, the transition experiences might also be influenced by what is most important to the student at *particular* time points and this will fluctuate over the period of their university studies. This fluctuation was also observed in other transitions research. For example, primary-secondary transitions research found that at the start of secondary school, the focus of the students and families were relationship transitions which changed to educational transitions later (Galton, 2010).

However, even with the ELT theory, which emphasizes multiple transitions, the need to develop it further arose. This development was based on transitions research with international students and students in other contexts, research which highlighted the impact of the students' transitions on the people significant to them, e.g., their family. This led to the development of the Multiple and Multi-dimensional Transitions Theory.

Multiple and multi-dimensional transitions (MMT) theory

The Multiple and Multi-dimensional Transitions (MMT) theory proposes that each individual experiences multiple transitions and that their transitions can trigger transitions for significant others. Conversely, significant others will be experiencing their own transitions and these transitions will trigger and/or have an impact on that individual's transitions. These mutual interactions of transitions between individual and significant others lead to an almost ongoing ripple effect across the ecosystem, highlighting the multi-dimensional nature of the theory. Further, these transitions are dynamic and are not taking place in a vacuum; they are in an environment that is constantly changing. This can be explained in the COVID-19 context with several environmental changes

Fig. 3 Educational and life transitions model (Jindal-Snape and Ingram, 2013) Note: This is not a static model and individuals' experiences will fluctuate over the period of their study and stay. The overall experience can shift depending on the strength of the positive or negative transition experience. The authors have permission to reproduce Fig. 3 under Creative Commons License.

taking place which, in turn, led to school and university closures. As can be seen in Fig. 4, the school teacher was dealing with a rapidly changing situation with transitions in their work and home contexts (Stones et al., 2020). Their students' transitions were also triggering further transitions in terms of adapting educational provision and pastoral support that suited the students' emerging and ongoing transition needs. This created transition support needs not only for their students but also for them. Further, their transition support needs in the context of significant others from their family were also emerging over time.

Fig. 5 shows the multiple and multi-dimensional transitions of a university lecturer and her students, as well as her family members, for example, the impact of home schooling on her professional life (Glazzard et al., 2020b). It also highlights that transition is an ongoing process with adaptation happening over time (Jindal-Snape, 2016). For instance, this parent might experience transitions personally and professionally in the future, due to their child's developmental stage, for example when childcare responsibilities change and the child prefers to spend more time with peers and starts asserting the need for independence from parents. These transitions due to their child's transitions will likely happen alongside other transitions in the lecturer's personal, social and professional life. Further, the parent's transitions will trigger transitions for the child. Therefore, the child and parent will experience transitions as a result of one another's transitions and these transitions will interact with the transitions of others in their ecosystem such as other children at school, their parents, and school professionals.

To understand MMT better, it can be visualized using Rubik's cube as a metaphor (Fig. 6; Jindal-Snape, 2016; Jindal-Snape et al., 2017). If each individual and their significant others is seen as one color, we can visualize six individuals and their significant others as well as their mutual interactions. If anything changes for anyone in that single color, that change can trigger changes across the Rubik's cube not only for that one color but for *all* colors and sides. Those changes then lead to transitions for all those in the connected ecosystems.

This will be explained further through examples from research that has used MMT as the theoretical framework.

Multiple and multi-dimensional transitions of young adults and significant others

In a study conducted with young adults with life limiting conditions, MMT was used as the framework to design a longitudinal study in which data were collected from young adults ($n = 12$) at three time-points and significant others that they nominated at two time points (Jindal-Snape et al., 2019). The significant others included parents, grandparents, siblings, physician, family doctor and social care professionals ($n = 23$, however not all participated at both time points). None of the young adults nominated school or university teachers but they made reference to them in their interviews. All participants were asked questions about their own and others' transitions. The sample size was small but rich data were collected. The findings suggested that young adults experienced multiple transitions such as health transitions, educational transitions, social and relationship transitions, and developmental transitions (including moving out, independent living, death and dying). Further, these transitions also interacted over time. Their transitions triggered transitions for significant others, such as one grandparent took early retirement to become a fulltime carer, one sibling decided to place their educational transition, and another sibling their social transition, on hold. Significant others were also experiencing unrelated multiple transitions which also interacted with the young adults' transitions.

Multiple and multi-dimensional transitions of university students who identify as LGBTQ+

In another study that investigated transitions of students to, and through, university, MMT theory was used to provide a theoretical framework (Glazzard et al., 2020a). Data were collected from five students through yearly interviews across three years of study (63,875 transcribed words), longitudinal audio diaries (23 audio diaries) and photo elicitation (22 photos). The students reported

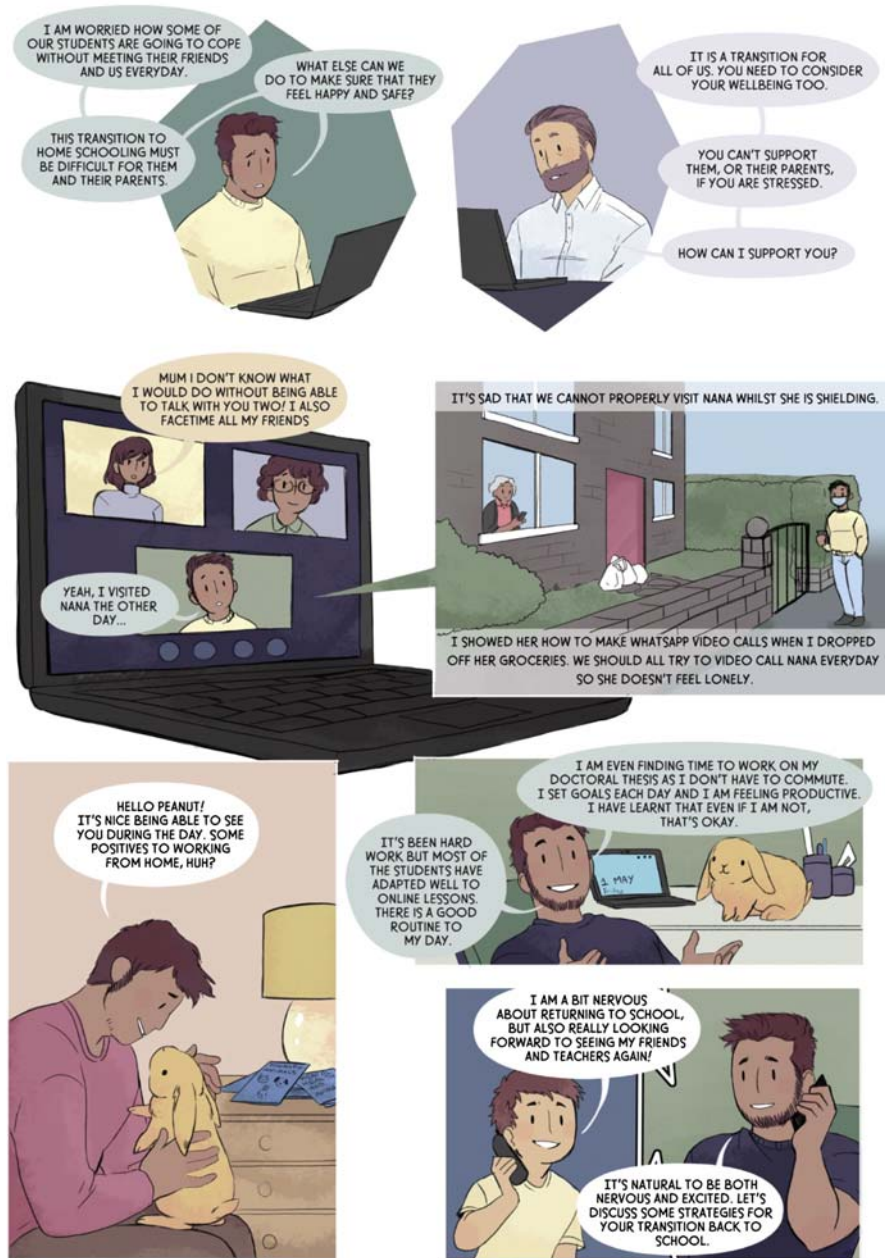

Fig. 4 School teacher and significant others' multiple and multi-dimensional transitions due to COVID-19 (Stones et al., 2020).

that they experienced multiple transitions, including academic (demands of the academic study and different approaches to teaching-learning and assessment), social (losing and developing new friendships), psychological, geographical (moving from home to a different city), professional (for those on qualifying programs), and identity (student identity, exploring and establishing LGBTQ + identity) transitions. Transitions were not linear or sequential and were experienced in multiple domains, every day. The students also reported having both positive and negative transition experiences at the same time, in different domains.

Multiple and multi-dimensional transitions of higher stage medical trainees

This study focused on the transitions of higher stage medical trainees from four health boards in Scotland (Gordon et al., 2017; see Fig. 6). This study used the MMT theoretical framework and undertook a longitudinal qualitative study which focused on participants' multiple and multi-dimensional transitions. Participants were 20 doctors within 6 months of completing postgraduate training. All participated in an interview at the start of the study, 18 participated in the interviews at the end of the study and those 18 also completed longitudinal audio/written diaries over a nine-month period. Participants submitted between 2 and 30 diary entries, an average of 13 diary entries. This study suggests that transitions happen over time and they are non-linear. Participants

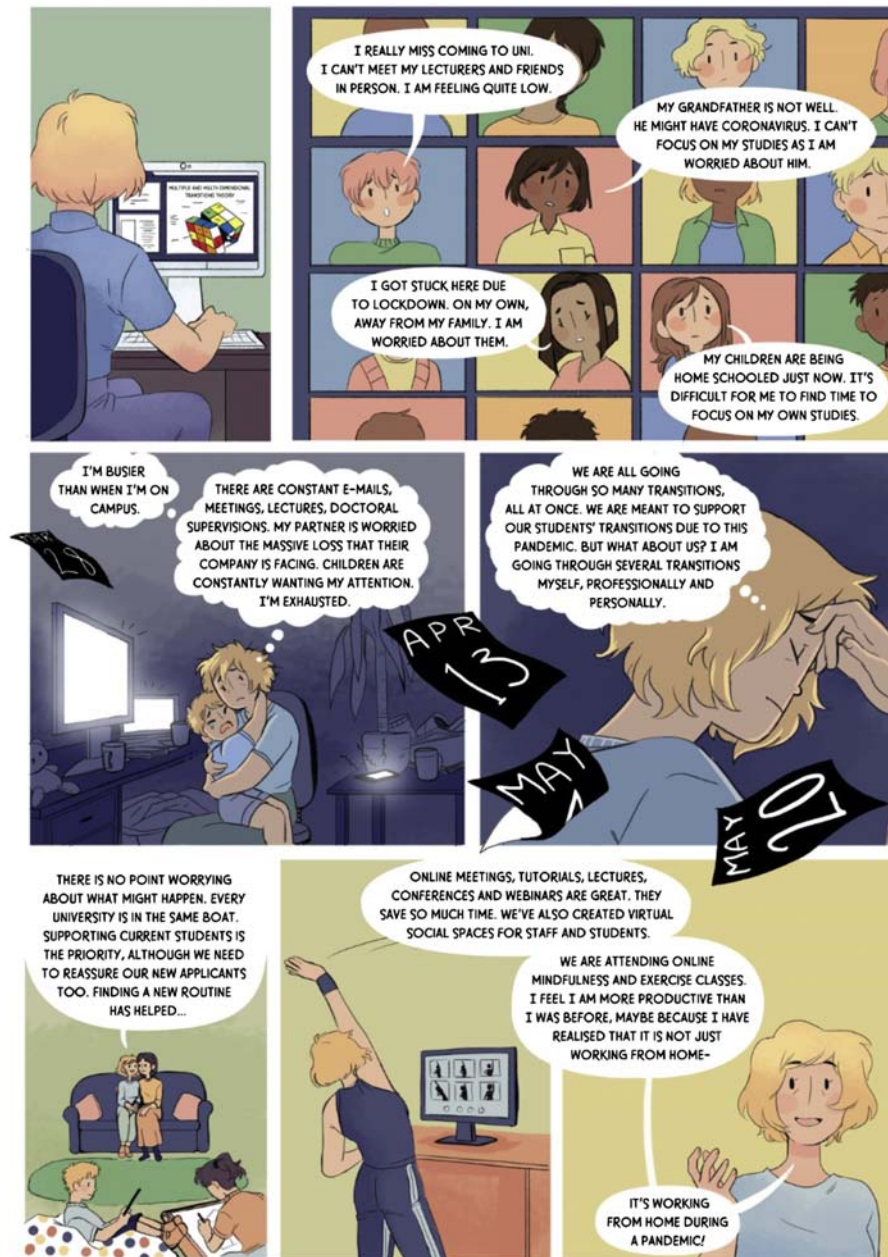

Fig. 5 University professor and significant others' multiple and multi-dimensional transitions due to COVID-19 (Glazzard et al., 2020b).

had both positive and negative multiple transition experiences, sometimes in the same or different domains of their life at the same time. These included work-related transitions (e.g., taking on new roles) and home related transitions (e.g., moving home due to change in organization and location). Transition experiences were complex and multi-dimensional, with their transitions interacting with or triggering transitions of significant others, such as a child spending more time in childcare setting due to changes in parental role and responsibilities. The participants were also affected by others' transitions, for example one indicated that they had to work flexibly to accommodate childcare due to their spouse's work transitions. Participants' work-related transitions also meant that they were able to spend less time with patients and had relationship transitions with existing colleagues when they took on a higher-level role in the same hospital, as well as those who moved hospitals, having to form new relationships.

Transition-to-trained-doctor (T3D) model

In keeping with the need to adapt and develop theories for one's own specific context, MMT was further expanded to include a Transition-To-Trained-Doctor (T3D) conceptual framework (see Fig. 7). The latter explicitly takes into consideration not only the multiple domains but also the multiple contexts by focusing on the contexts in Canada, Netherlands and the UK (Gordon et al., 2020). Using MMT as the theoretical framework, secondary data analysis was undertaken of 55 interview transcripts. Participants

MULTIPLE AND MULTI-DIMENSIONAL TRANSITIONS FROM TRAINEE TO TRAINED DOCTOR: A QUALITATIVE LONGITUDINAL STUDY

Fig. 6 Multiple and multi-dimensional transitions of higher stage medical trainees (Jindal-Snape et al., 2017).

Fig. 7 The T3D model. [Gordon et al. \(2020\)](#).

described the transition in four domains of their work and personal lives (physical, cultural, psychological, and social; [Jindal-Snape, 2016](#)) and four contexts, taking cognizance of [Bates and Ellaway's \(2016\)](#) multiple clinical context perspective (workplace, role, educational and home). As can be seen from [Fig. 7](#), the individual is situated in one or multiple contexts in line with their prominence for that individual at any given time, along with the overarching wider national context.

Within each context, all four transition domains exist, implying that an individual has multiple types of transitions happening in every context they are situated in every day. Further, the transition domains and contexts interact with each other. The multi-dimensional nature of transitions and interaction with the transitions of significant others is depicted through open circles. The T3D model takes cognizance of intentional fluidity and mobility.

The 12 pillars of successful multiple and multi-dimensional transitions

Our research suggests that certain dispositions and environmental factors can lead to successful educational and life transitions ([Glazzard et al., 2020a](#); [Gordon et al., 2017](#); [Jindal-Snape et al., 2020, 2021](#); [Jindal-Snape and Cantali, 2019](#); [Jindal-Snape et al.,](#)

Fig. 8 The 12 pillars of successful multiple and multi-dimensional transitions. Divya Jindal-Snape & Clio Ding.

2019; Jindal-Snape and Miller, 2008). These can be summed up as 12 pillars of transitions, which interact and are interdependent but have been separated here for ease of understanding. The 12 pillars are related to dispositions, beliefs, support systems and environmental affordances including culture and discourse. It is worth noting that for successful transitions, not all pillars have to be present or have to be equal at the same time. Different pillars might be prioritised during different types of transitions. These pillars are useful for an individual across the life course and when navigating different types of transitions. It is also important to note that these are not within-person or fixed, rather they can be, and are, created and maintained over time (see Fig. 8).

The 12 pillars of successful MMT are:

1. Multiple and Multi-dimensional Transitions Habits of Mind (MMT-HOM)
2. Multiple and Multi-dimensional Transitions Habits of Heart (MMT-HOH)
3. Attitudes and beliefs about transitions (e.g., MMT Growth Mindset)
4. Perception of ability and skills to navigate transitions
5. Experience and outcomes of other multiple and concurrent transitions
6. Discourse about transitions at home, school, workplace, in the wider community, media
7. Social Capital (social connections/networks/relationships)
8. Significant others' ability to support transitions (e.g., family, professionals, peers)
9. Significant others' experiences and outcomes of their own transitions
10. Opportunities to discuss transitions in everyday life
11. Experience of diverse pedagogical/andragogical approaches/work practices
12. Organizational, familial and community culture

Habits of Mind have been defined as "thinking" dispositions to act intelligently when faced with a new situation or problem, and include a composite of diverse range of skills, attitudes and past experiences (Costa and Kallick, 2009). The skills and attitudes that can be developed to ensure MMT-HOM include providing opportunities to learn how to solve problems creatively, adaptability, open mindedness, curiosity, collaboration, resourcefulness, applying past learning to new situations, agency, persistence, and comfort with ambiguity and uncertainty (this is not an exhaustive list).

Habits of Heart have been defined as dispositions that can develop and enhance social-emotional intelligence. MMT-HOH focus on psychological adaptations and transitions related to, for example, change in relationships (and social capital), feelings about one's transition experiences, compassion for others, and most importantly self-compassion. Although separated here, MMT-HOM and MMT-HOH are habits that interact with one another. These are habits that can be developed and nurtured across the life course, whether in nursery/school/higher education/professional education and require diverse pedagogical/andragogical approaches/work practices.

Further, MMT-HOM and MMT-HOH will help an individual understand and access their social capital to navigate their transitions in new environments and with new people. On the other hand, an individual's social capital is also likely to influence their MMT-HOM and MMT-HOH. They will also have an impact on an individual's attitudes and beliefs about transitions (e.g., understanding of the dynamic nature of transitions and that transitions outcomes are also not static and they have the agency to change negative outcomes to positive over time, i.e., what I propose here as a Multiple and Multi-dimensional Transitions Growth Mindset (MMT-GM); see Dweck, 2017 for a discussion of Growth Mindset). THOH and THOM also have an impact on an individual's

perception of their ability and skills to successfully navigate transitions. For instance, an individual, when confronted by a new and unexpected situation, is more likely to have a positive attitude about transitions and would believe that they can manage them if they know how to solve a problem creatively and/or know how to adapt to change, and are self-compassionate when finding it difficult to solve the problem.

However, it is important to be mindful that the interactions between individuals and structures create dispositions over time and such interactions will have an impact on individual's attitudes toward transitions and perception of their own ability to navigate them successfully. These include unspoken rules and valuing of particular attributes in their environment, resulting in particular discourse about transitions in their environment, and other dimensions such as their experiences and outcomes of other multiple and concurrent transitions and significant others' ability to support the individual's transitions. The latter is affected by the significant others' experiences of their own transitions. Further, there are other pillars that interact with all of these, such as those related to opportunities to discuss about transitions in everyday life (e.g., opportunities to discuss excitement and concerns, strategies from those who have experienced those transitions), and organizational (whether of school or workplace), familial, and community culture.

These pillars are complex and impact on each other in multiple ways. They can be generated consciously and purposefully but require multiple approaches and partnership working between families, professionals, organizations, community, and media. Conceptualization of pillars in this way can highlight what resources an individual has to navigate transitions successfully and what can be done to increase them. However, it is important to note that it would be easier to influence some pillars than others.

It is a conceptual framework that can be used by teachers, for instance, to select pedagogical approaches that can develop young children's MMT-HOM and MMT-HOH. The teachers can also provide them with opportunities to discuss their beliefs about transitions, excitement/concerns, and strategies used by their peers, families and professionals when experiencing similar transitions. Further, teachers can ensure the discourse in the school about transitions is positive as well as involving parents and other stakeholders to support this discourse. However, it is important to realize that this discourse in the natural environment will be influenced by significant other's own transitions experiences, beliefs, attitudes and dispositions.

Conclusion

In this article, I have attempted to start a debate about the conceptualization and theorization of transitions. My argument is that until, and unless, we do this, we cannot advance transitions as a distinct area of study that can be pursued with rigor. This then has implications for the policy and practice that might be based on research in the area.

It is important, as is expected in any field, that authors explicitly present their conceptualization and operationalization of transitions. Ideally, they should also ask what transitions and successful transitions mean to their participants. It is also important that future research has a balanced discourse which focusses on both positive and negative aspects of transitions.

Further, it is crucial that future transitions research builds on previous transitions research, not just as a token mention in the introduction of an article but starting from the moment a researcher starts considering research questions and appropriate research design. It is important that future researchers are also mindful of the theoretical framework they are using and that it is threaded throughout their study. However, it is even more important that they critique the existing theories, for example, MMT, with regard to their particular context, to provide a more granular and robust framework that is fit-for-purpose.

In the context of policy and practice, it is important to understand the ongoing, dynamic nature of multiple transitions that necessitates support not only with one transition or at one particular time. Further, the transitions of significant others and their interplay with the students' transitions need to be understood. Professionals and families require support with their transitions if they can be expected to provide good transitions support to students.

I have also introduced some new concepts, which build on our research, conceptualization and theorization, namely MMT-HOM, MMT-HOH, MMT-GM and the XII Pillars of MMT. They provides insights into how, from a very young age, professionals can support the development of, at least some, habits and dispositions that will help them with navigation of transitions throughout their life. Further, it also can provide insights into where individuals might have less resources and how they can be supported to develop them.

Introduction

With strong connections to past research (e.g., [Carpenter and Moser, 1984](#); [Driver, 1989](#)), contemporary efforts to describe and explain how students' learning unfolds over time have focused on *learning progressions*. Over the past two decades, work to develop and use learning progressions (and associated constructs) has spread from science and mathematics to varied subjects (see [Table 1](#)), conducted in countries around the world (see [Table 2](#)). Extant examples of learning progressions span preschool (e.g., [Allen, 2017](#); [Moreno et al., 2021](#)) through university (e.g., [Magana, 2017](#); [Sevian and Talanquer, 2014](#)) and beyond (e.g., in-service teachers; [Bargagliotti, 2021](#); [Furtak et al., 2012](#); [Schneider and Plasman, 2011](#)). In addition to numerous journal articles

Table 1 Examples of work on learning progressions in subjects other than math and science.

Subject	Example(s) of work on learning progressions
Art	Maras (2021)
Language	Bailey and Heritage (2014) , van Rijn et al. (2014)
Computer science	Rich et al. (2018)
Engineering	Magana (2017)
Geography	Larsen and Harrington (2018) , Maeng (2020) , Solem et al. (2014)

and reports, special journal issues (e.g., Alonzo, 2018; Bernholt and Sevan, 2018; Clements and Sarama, 2004; Duncan and Hmelo-Silver, 2009a; Mitchell, 2018; Oates and Seah, 2021; Talanquer, 2013), books (e.g., Alonzo and Gotwals, 2012; Furtak, 2017; Maloney et al., 2014; Siemon et al., 2019; Solem et al., 2014), and conferences (e.g., Learning Progressions in Science, 2009; Learning Progressions Footprint Conference, 2011) have been devoted to this work.

As with other constructs with widespread appeal (e.g., “inquiry”), a range of meanings has been attached to “learning progressions,” and the distinction between this and similar constructs is not always clear. In this article, I define a learning progression to be a framework that represents student learning of a competency through a series of components (e.g., levels, constituent “building blocks”) that describe the increasingly more difficult, complex, and/or sophisticated performances expected as students learn. This broad definition encompasses wide variation in frameworks that have been labeled “learning progressions”; it also includes *learning trajectories* (often in mathematics), for example Simon (1995) and Maloney et al. (2014). Although informed by disciplinary perspectives, learning progressions describe competencies from the point of view of the student, rather than disciplinary logic (e.g., Bailey and Heritage, 2014; Fonger et al., 2018). To capture the wide range of knowledge, practices, and other learning targets that learning progressions may represent, I draw on the notion of competencies as “complex cognitive abilities” and “affective and volitional dispositions” that underlie “real-world” performance (Blömeke et al., 2015, p. 6), such as engaging in the authentic work of a discipline (e.g., Wilson and Lehrer, 2021). *Teaching-learning sequences*, structured sequences of instructional activities with “well-documented teaching suggestions and expected student reactions” (Psillos and Kariotoglou, 2016, p. 12), and other frameworks for “teaching learning progressions” (Wickman, 2014) include attention to changes in students’ competencies. However, I exclude these frameworks from my definition as having a primary goal of describing teaching, rather than learning.

Learning progressions have been considered promising tools for supporting student learning by informing standards, curriculum, instruction, assessment, and teacher learning (e.g., Daro et al., 2011). Despite the promise of learning progressions to support various parts of the educational system, these tools have been critiqued for their depiction of students’ competencies and learning of those competencies (e.g., Hammer and Sikorski, 2015). Most crucially, concerns have been raised about learning progressions’ potential to perpetuate, and even exacerbate, educational inequities (e.g., Delgado and Morton, 2012; Myers, 2015).

In this article, I explore variations in and affordances of learning progressions, considering how different types of learning progressions are suited for different applications. I identify equity as a key challenge for learning progression research as the field moves from initial efforts to develop learning progressions to wider applications of these tools in classrooms and other educational spaces. Using examples of promising research, I call for additional research that is required if learning progressions are to have the envisioned impact on student learning.

Variation in learning progressions

There is significant variation in extant examples of learning progressions, including in the competencies they describe (see Table 3). However, learning progressions typically include some description of the resources for learning and/or nascent forms of the

Table 3 Examples of types of competencies described in learning progressions.

Type of competency	Example(s) of competency
Concept	• Mathematical equivalence (Fonger et al., 2018)
Practice	• Buoyancy (e.g., Gao et al., 2020; Paik et al., 2017; Yin et al., 2013) • Argumentation (e.g., Berland and McNeill, 2010; Bravo-Torija and Jiménez-Aleixandre, 2018; Osborne et al., 2016; van Rijn et al., 2014)
Ways of thinking or reasoning	• Modeling (Magana, 2017; Pierson et al., 2019; Schwarz et al., 2009) • Probabilistic thinking (Bai, 2020) • Statistical reasoning (Callingham et al., 2021) • Geocognition (Maeng, 2020)
Affective/volitional disposition	• Quantitative reasoning in science (Jin et al., 2019a; Mayes et al., 2014) • Epistemic agency (Taylor and Brand, 2021)
Combination	• Content and practices (e.g., Briggs and Furtak, 2019; Gotwals and Songer, 2013; Kaldaras et al., 2021; Wilson and Lehrer, 2021; Wyner and Doherty, 2017)

competency students are likely to have upon entering the progression (e.g., “lower anchor”), a description of the competency that is the goal for the progression (e.g., “upper anchor”), and portrayals of the intermediate competencies through which students might move as they progress from the lower to the upper anchor (e.g., Duschl et al., 2011; Jin et al., 2019b; Ketterlin-Geller et al., 2020). Traditionally, these descriptions are portrayed using one or more series of ordered levels (sometimes labeled *construct maps*, Wilson, 2009, or *progress variables*, e.g., Jin and Anderson, 2012); however, as discussed below (Section **Representing diversity**), other representations are being explored.

Over the years, others have characterized, and often classified, different types of learning progressions (e.g., Battista, 2011; Duschl et al., 2011; Lobato and Walters, 2017; Shavelson and Kurpius, 2012). Below, I highlight distinctions among learning progressions that are particularly important for their application (see **Applications of learning progressions** section) using four continua, instead of distinct categories.

Learning progression components

This continuum refers to variation in the nature of the components that make up a learning progression. On one end of this continuum, learning progressions are made up of smaller components (“building blocks”) that students must master or put together to reach the overall desired competency (e.g., Popham, 2007; Scoular, 2021). These learning progressions require attention to the structure of a competency, for example, what smaller components it comprises and which components are prerequisite to others. From this perspective, students accumulate the smaller building blocks to learn the overall desired competency.

On the other end of the continuum, learning progressions describe “successively more sophisticated” instantiations of a competency (e.g., Clements and Sarama, 2014; National Research Council, 2007, p. 219): a competency “in progress.” In this view, intermediate levels of a learning progression serve as stepping stones (Campbell et al., 2016; Wiser et al., 2012), which may include (or consist of) non-canonical ideas or practices important for developing more canonical versions of the competency (e.g., Duncan and Rivet, 2013). Learning progressions at this end of the continuum require attention to the way students engage with, and revise and/or refine, the competency as they learn.

Among the learning progressions in the middle of this continuum are those that combine the two perspectives, highlighting the ordering of components but also describing increasingly sophisticated instantiations of those components (e.g., Neumann et al., 2013). The knowledge integration approach (e.g., Lee and Liu, 2010) also falls in the middle of this continuum; in this perspective, increasing sophistication is the integration of increasing numbers of concepts (i.e., component building blocks).

Emphasis on ordering vs. pathway

Although most learning progressions include some motivation related to curriculum and instruction, that is ordering concepts so that children can learn most optimally (Allen, 2017), and encourage attention to “growth over status” (Briggs and Furtak, 2019, p. 146; Shepard, 2018), there is variation in the extent to which learning progressions are treated as pathways for learning. At one end of this continuum, researchers focus on the ordering of components, typically based on their (empirically determined) difficulty (e.g., Johnson, 2013; Kamei and Pavlovic, 2021; Liu, 2013). An underlying assumption of this approach is that the resulting ordered set of components will constitute a pathway for learning (e.g., Chiu and Wu, 2013); however, empirically derived ordering typically reflects the “status quo” instructional environment, which may not be optimal for student learning.

Researchers at the other end of the continuum focus on designing a pathway for learning, arguing that “the benchmarks of learning tend not to emerge unless someone carefully engineers and sustains the conditions that support them” (Lehrer and Schauble, 2012, p. 705). For example, design studies (e.g., Cardace et al., 2021; Clements et al., 2004; Taylor and Brand, 2021; Yoon et al., 2019) engineer instruction to support student learning of a competency and document, as a learning progression, the pathway that students take to learn that competency.

In between these two extremes, researchers may develop a learning progression by focusing on the difficulty of components and then work to refine the learning progression as a pathway for learning by using it to design instruction and documenting the student learning that results (e.g., [Castro-Faix et al., 2021](#)). Therefore, at different stages (e.g., initial development vs. refinement), work on a given learning progression may be situated at different points along the continuum.

Generalizability

In contrast to earlier work, such as Piaget's stages of development, "learning progressions are not developmentally inevitable but depend on instruction" ([Smith et al., 2006](#), pp. 5–6). At the same time, there may be (universal) developmental constraints ([Duncan and Gotwals, 2015](#)), and learning progressions differ in the extent to which specialized instruction is assumed necessary.

At one end of a generalizability continuum, many learning progressions are designed to be universally applicable. They are developed without much attention to context, under the assumption that "although some variability exists based on experience, culture, and instructional environments ... many students have similar patterns of development, learning, and thinking that can be generalized across the population" ([Ketterlin-Geller et al., 2019](#), p. 2).

At the other end of the continuum, acknowledging that teaching and learning are highly contextualized, some learning progressions describe learning under specific circumstances. Learning progressions of this type might apply to students engaging with a particular curriculum and/or students in a particular place (e.g., [Ladachart et al., 2020](#)). In these approaches, the learning progression may include not only the framework but also specific curriculum materials and/or other resources (e.g., [Fonger et al., 2018](#)). In the middle of this continuum is work that attends to context while trying to understand universal aspects of students' learning (e.g., [Taylor and Brand, 2021](#)).

Scope and grain size

As others have identified (e.g., [Gotwals, 2012](#)), learning progressions can be developed with varying scope (amount of time, whether expressed as ages or grade levels). For the most part, learning progressions with a broader scope have a larger grain size: the scope of individual components and/or the distance between them. Broader learning progressions generally contain less detailed accounts of, and larger shifts in, components, since grain size typically increases with increasing breadth to keep the number of levels manageable. For example, learning progressions associated with the *Next Generation Science Standards* ([NGSS Lead States, 2013](#)) describe students' competencies in four large grade bands: K–2, 3–5, 6–8, and 9–12.

At one end of the scope and grain size continuum, learning progressions cover many years (e.g., [Chang et al., 2020](#); [Hermann-Abell and DeBoer, 2018](#); [Kim et al., 2017](#); [Maras, 2021](#); [Mohan et al., 2009](#); [Paik et al., 2017](#); [Rich et al., 2018](#); [Smith et al., 2006](#)). At the other end of this continuum, learning progressions have a scope as narrow as a few weeks (e.g., [Alonzo and Steedle, 2009](#); [Yin et al., 2013](#)). In addition to learning progressions with scopes in between these two extremes, the middle of the continuum includes proposals to pair learning progressions with large and small grain sizes (e.g., [Fonger et al., 2018](#); [Gotwals, 2012](#)).

Applications of learning progressions

Since the early days of interest in "learning progressions," these frameworks have been promoted as tools to inform standards, curriculum, instruction, and assessment: both broad applications, such as achieving curricular coherence across multiple grades ([Smith et al., 2006](#); [Confrey et al., 2022](#)), and smaller-scale, classroom applications, such as support for teachers' formative assessment practices (e.g., [Black et al., 2011](#); [Clements et al., 2011](#); [Furtak, 2012](#); [Heritage, 2008](#); [Shepard, 2009](#); [Sztajn et al., 2012](#)). As described in the sub-sections below, many of these proposed applications are now coming to fruition. In this section, I provide a brief overview of some affordances of learning progressions, highlighting the type(s) of learning progressions well-suited to each application.

Standards, curriculum, and instruction

As others have noted, learning progressions are similar to [Bruner's \(2003\)](#) idea of a spiral curriculum (e.g., [Chang et al., 2020](#); [Huynh et al., 2015](#)), in which topics are revisited with increasing sophistication as students move through school. The ordering of components in learning progressions can support the development of standards and curricula so that students learn important building block ideas as they move toward desired competencies by the end of schooling (e.g., [Confrey and Maloney, 2014](#); [Foster and Wiser, 2012](#)). For example, development of new standards for mathematics ([National Governors Association Center for Best Practices and Council of Chief State School Officers, 2010](#)) and science ([NGSS Lead States, 2013](#)) in the United States was informed by, and in terms of, broad learning progressions. Similarly, in Australia, learning progressions ([Australian Curriculum and Assessment and Reporting Authority, 2020a,b](#)) underpin the national curriculum.

Standards lay out a pathway for learning and may be informed by learning progressions that consider difficulty or complexity of components. To support coherence across grades and levels of schooling, learning progressions for this application have a large grain size. Standards are assumed to be broadly applicable (at least to students in the jurisdiction of the standards); therefore, learning progressions used to inform standards should be generalizable. In addition, because standards depict goals for student

learning, it is important that the components depicted are canonically accepted, rather than stepping stones that support development of canonical competencies but are themselves non-canonical (Foster and Wiser, 2012; see [Learning progression components](#) section).

In the classroom, a learning progression can influence instruction, whether through formal curriculum materials (such as those included with or as part of a learning progression) or teachers' own planning. The pathway laid out by a learning progression can serve as a guide when planning the specific learning experiences that will support movement within the learning progression. For example, Building Blocks (Clements and Sarama, 2007) and Carbon TIME (n.d.) are curricula designed to support movement through a learning progression. Both learning progressions that comprise building blocks and those that comprise increasingly more sophisticated or complex components can be used to inform instruction. To inform curriculum and instruction, learning progressions must have a small enough grain size to support the identification of specific instructional goals and strategies.

Formative (classroom) assessment

A highly touted affordance of learning progressions is their ability to support processes of formative assessment. A teacher could use a learning progression like a roadmap (e.g., Black et al., 2011): locating students' current competencies within the terrain of typical learning of the competency (e.g., Battista, 2011; Shepard, 2008) and, subsequently, using that location to identify appropriate support for students' movement from their current location toward mastery of the competency. This support could occur through targeted feedback (e.g., Furtak et al., 2018) or further instruction (e.g., Sztajn et al., 2012). By alerting teachers to potential student performances and, thus, influencing what ideas and practices are elicited and attended to, learning progressions might broaden assessment practices to include components characteristic of lower-performing students (Furtak, 2012; Sztajn et al., 2012; Wilson et al., 2013, 2015). To explore these affordances, researchers have developed and studied learning progression-aligned diagnostic assessment systems (e.g., Bennett, 2016; Confrey et al., 2017a; Confrey and Maloney, 2015; Daro et al., 2011; Wilson and Lehrer, 2021) and investigated how teachers make use of learning progressions to support formative assessment practices (e.g., Alonzo et al., 2022; Bailey and Heritage, 2014; Confrey et al., 2021; Covitt et al., 2018; Furtak et al., 2014).

For classroom use, learning progressions must capture "critical qualities of students' ways of thinking without being either so broad as to provide very little guidance for instruction and assessment, or so overwhelmingly fine-grained as to impede ready use" (Empson, 2011; Wilson and Lehrer, 2021, p. 2). The idea of learning progressions as pathways of learning is central to their use in formative assessment. Different types of learning progression components are useful for formative assessment, so long as the learning progression accurately describes the learning of students engaged in the formative assessment process. This could be accomplished either with a learning progression tailored to a particular environment or with a learning progression that can be generalized to that environment.

Summative (classroom and large-scale) assessment

In addition to informing formative assessment, learning progressions have the potential to inform summative assessment, at both classroom (e.g., Alonzo, 2019; Briggs et al., 2015) and large-scale (e.g., Alonzo et al., 2012) levels. Learning progressions describe a continuum of performance, so they can be used as the basis for criterion-referenced interpretations of students' performance and growth anywhere along the continuum (Briggs et al., 2015). Because students can be evaluated with respect to criteria laid out in the learning progression, rather than grade level expectations, assessments can be designed to capture a wide range of student performances, including those below grade level, and growth can be acknowledged, even when it does not result in fully meeting grade level expectations (e.g., Alonzo, 2019; Department of Education and Training, 2018; Waters, 2018).

Learning progressions used to inform summative assessment must be applicable to the students being assessed. At the classroom level, this means that the learning progression matches how learning is expected to unfold in that instructional context (i.e., specific to that context or generalizable across contexts); at the large-scale level, this means that learning progressions must be broadly generalizable (i.e., applicable to a wide range of learning contexts). In both cases, learning progressions should be at a grain size that matches the scope of the assessment: a classroom assessment covering a unit of instruction would have a smaller grain size than a national or international assessment covering a year or more of instruction. At the same time, reliability is crucial for summative assessment, and it is easier to characterize students' performance relative to a learning progression reliably when there are larger distinctions between components, such as levels, i.e., larger grain size. With smaller grain size, it becomes less likely that students respond at the same level across items or that graders consistently distinguish between responses at adjacent levels, since the difference between the levels is small.

Teachers' knowledge/tool for professional development

Teachers' understanding of a learning progression is key to its classroom use (e.g., Furtak et al., 2014; Heritage, 2011). At the same time, learning progressions can promote teachers' own learning: content knowledge (e.g., Wilson et al., 2013), pedagogical knowledge (e.g., Bennett, 2010); and pedagogical content knowledge (PCK; e.g., Gunkel et al., 2018; Sztajn et al., 2012), including content knowledge for teaching (Suh and Seshaiyer, 2015), awareness of student ideas and reasoning (e.g., Alonzo et al., 2022; Furtak, 2012; Ivars et al., 2020), and understanding of students' reasoning (e.g., Wilson et al., 2013) and learning (e.g., Bailey and Heritage, 2014). Researchers have also observed shifts in teachers' perspectives on teaching, learning, and/or academic performance (e.g.,

Alonzo et al., 2022; Furtak, 2012; Wilson et al., 2017). Teachers' learning may occur through their classroom use of learning progressions and/or their engagement with professional development (often provided to support learning progression use). The influence of learning progressions may be indirect, for example, when used to structure professional development experiences that lead to important shifts in practice without teachers' direct use of learning progressions (e.g., Alonzo et al., 2022; Furtak et al., 2015).

In addition, learning progressions may provide a conceptual framework that seeds teachers' own inquiries and knowledge generation. From this perspective, teachers do not learn only as they receive learning progressions from researchers but also as they make sense of these tools (e.g., Sztajn et al., 2012) in relation to their own practice. As models, LPs may, like models in science, be used to "notice and characterize phenomena that don't fit the model" and serve as a conceptual framework to ask and investigate questions (Alonzo and Elby, 2019, p. 6). For example, the typical pathway of student learning laid out in a learning progression may provide "a good starting point for deeper interrogation of learners' unique pathways" (Scoular, 2021, p. 118). Benefits of using learning progressions may even come not from teachers' direct use of these tools, but rather from the development of PCK and use of this knowledge to inform practice more generally (Alonzo and Elby, 2019; Parr, 2011). Teachers may benefit from learning progressions of all types. For example, they might explore vertical coherence through broader learning progressions (e.g., Birkhead et al., 2017) and explore details of students' competencies and learning through narrower learning progressions (Moreno et al., 2021).

Coherent educational systems

While learning progressions have potential for the individual applications described above, another central affordance is the ability to align multiple parts of the educational system to a learning progression to achieve greater coherence among standards, curriculum, instruction, assessment, and teacher professional development (e.g., Bennett, 2010; Black et al., 2011; Confrey and Maloney, 2014; Department of Education and Training, 2018; Jin et al., 2019b; National Research Council, 2006; Simeon, 2021). Such alignment among parts of the educational system is essential to visions of personalized instruction (e.g., Achieve, 2015; Department of Education and Training, 2018; Hughes et al., 2020), where students are engaged with learning opportunities matched to their current competencies, rather than age or grade level. In addition to the nationwide effort ongoing in Australia (e.g., Department of Education and Training, 2018), the diagnostic assessment systems described above (Section **Formative (classroom) assessment**) are examples of these ideas being put into practice.

Because of the variation in learning progressions required for different parts of the educational system, nested learning progressions will likely be needed, in which smaller learning progressions, which meet the requirements of classroom-level work, are embedded within larger learning progressions that meet the requirements of large-scale work (Gotwals, 2012). To achieve this vision, researchers (e.g., Confrey and Maloney, 2014; Lehrer et al., 2014) have begun to conceptualize learning progressions as boundary objects that facilitate work across the different communities of practice in an educational system.

Equity critiques of learning progressions

While learning progressions have generated interest because of their potential and, to some extent demonstrated ability, to support many parts of an educational system responsive to students' learning needs, they have also been subject to important critiques (e.g., Empson, 2011; Hammer and Sikorski, 2015; Pierson and Clark, 2019; Shavelson and Kurpius, 2012; Sikorski, 2019). As models of complex phenomena, learning progressions "do not just illuminate, they also eliminate information" (Alonzo and Elby, 2019; Corcoran et al., 2009; Empson, 2011; Lehrer and Schauble, 2015, p. 731).

Although there are many implications of omitting information about students' competencies and learning, I focus on equity implications in this article. In particular, learning progressions illuminate common patterns in students' competencies (e.g., Bailey and Heritage, 2014; Battista, 2011; Chiu and Wu, 2013; Gunkel et al., 2012); however, by reducing the complexity of the student competencies they represent, learning progressions inevitably leave out ways of knowing, reasoning, engaging with disciplinary practices, and learning (e.g., Duncan and Gotwals, 2015; Empson, 2011; Hammer and Sikorski, 2015; Lombard et al., 2018; Metz, 2009; Pierson et al., 2017; Salinas, 2009). In this section, I argue that such omissions have the potential to render some students less visible, less recognized, and less likely to benefit from learning progression-aligned instruction and that these impacts are especially likely for students from marginalized communities, who often are excluded from the research used to develop learning progressions (e.g., Delgado and Morton, 2012; Williams, 2018). Thus, rather than contributing to better learning outcomes for all students, as some have argued (e.g., Corcoran et al., 2009), learning progressions could create greater inequities.

In this section, I explore the consequences of reducing two types of complexity to create aggregate descriptions: variation in students' competencies and variation in students' learning. In particular, I focus on what happens when these aggregate descriptions omit alternatives, in terms of both the content and ordering of components of the learning progression.

Content of learning progression components

A learning progression foregrounds a set of building blocks or increasingly sophisticated ways of engaging with a competency and, necessarily, backgrounds others. By illuminating the components of a competency that precede full mastery, learning progressions provide insight into stepping stones in (and building blocks of) students' learning. Awareness of these components underlies key applications of learning progressions from informing large-scale standards, curriculum, and assessment to influencing teachers' knowledge and classroom assessment practices. Thus, students whose developing competency does not match the components

of a learning progression may experience exclusion at multiple levels of the educational system. Such exclusion is particularly problematic, given that learning progressions are designed to support students in using prior ideas, practices etc., as the foundation for learning new ones (e.g., Schramm et al., 2018) and because learning progressions may treat “students’ place-based experience, indigenous knowledge, and traditional ways of thinking” as noise (Ladachart et al., 2020, p. 995).

Standards, curricula, and instruction

Learning progression-informed standards, curricula, and instruction are designed to provide bridges from one component to the next in order to support students in developing new competencies on the basis of their prior ones. When the components of students’ developing competency do not match those in a learning progression, students’ opportunity to leverage their own resources may be curtailed. This exclusion may be particularly problematic toward the beginning of a learning progression, where the “lower anchor” describes the expected foundation for learning a competency (e.g., Duncan and Hmelo-Silver, 2009b).

A metaphor is useful here: learning progressions are “formations of stepping stones” across a river, where the goal is to help “students move from their current state of knowledge and skill to a learning goal on the other side of the river” (Achieve, 2015, p. 2). Here, and below, I use “stepping stones” to refer to both building blocks and less sophisticated versions of a competency. Extending the metaphor, the left side of Fig. 1 shows instruction providing a bridge from the bank of the river to the first stepping stone, as well as between stepping stones. However, a student down the river (right side of Fig. 1) has no bridge to get to the first stepping stone and must either jump from the bank into the river, hoping to hit a stepping stone, or travel down the riverbank to the starting point and cross the bridge from there. In both cases, the student is at a disadvantage: having to make a big leap to the first stepping stone and perhaps falling short (and into the river) or needing to travel a large distance on land before jumping to the first stepping stone (and potentially arriving after the rest of the class has moved on).

Assessment

Learning progressions have the potential to inform day-to-day student-teacher interactions by focusing teachers’ attention on significant features of students’ learning. However, there is a danger that learning progressions may narrow focus on those features, causing others to be missed (e.g., von Aufschnaiter and Alonzo, 2018). Continuing with the river metaphor, if teachers are only looking for students at the stepping stones represented in a learning progression, they may miss students like the one in Fig. 1 who is attempting to cross from a different starting point or, having ventured from the bank, is stuck in the middle of the river on a potentially productive stepping stone not included in the learning progression. If these students and their nascent competencies are not recognized, their ideas may not be highlighted in class discussions (e.g., Empson, 2011; Furtak, 2012; Sztajn et al., 2012) or taken up in other forms of instruction.

In addition, narrowed attention has the potential to result in misinterpretation of student achievement and learning needs. For example, despite their potential utility for large-scale assessment (e.g., Alonzo et al., 2012) and/or automated diagnostic/formative assessment (e.g., Chin et al., 2021b), ordered multiple-choice (OMC; Briggs et al., 2006) items may provide misdiagnoses of students whose developing competencies are not represented in the option choices and who are forced to choose an option that does not represent their engagement with the competency. When assessment results are then used to make instructional decisions, students whose competencies have been misdiagnosed are less likely to receive appropriate instruction.

Fig. 1 River metaphor showing consequences of a mismatch between a student's starting position and that assumed in a learning progression
 Note: The pathway on the left is represented in the learning progression and supported by instruction (represented by the thick black lines). The student starts from a different point than that assumed in the learning progression and must take one of the three paths indicated by the thinner dashed lines.

Ordering of learning progression components

Layered on top of what components are included/excluded is the ordering of those components. Learning progressions “represent overarching aggregate arcs in the curriculum, which are rarely replicated in individual students’ context-dependent and non-linear learning trajectories” (Pierson et al., 2019, p. 834). Even if students’ learning can be described accurately by the components of a learning progression, if their pathways through those components are not represented, opportunities to learn may be diminished: both directly, through standards, curriculum, and instruction, and indirectly, through assessment.

Standards, curricula, and instruction

Laying out standards or curricula requires identifying one ordering (of content for students at different grade levels in standards, of lessons in a curriculum), based on the prediction of a pathway that will support as many students as possible to reach the upper anchor of the learning progression. However, learning unfolds through complex interactions with students’ prior competencies and resources for learning, interactions with teachers and peers, and other features of the learning environment (Eames et al., 2021). What is optimal for some students may be much less successful for others. For example, when learning progressions are created to portray cross-sectional differences in student achievement under status quo conditions, the resulting pathway is reflective of current instruction, which is often less successful for students from marginalized groups. There is also a danger that instruction will steer students along the pathway set out by the learning progression, at the expense of opportunities for students to “express, test, and revise their own ways of thinking” (Lesh and Yoon, 2004, p. 205; Sikorski and Hammer, 2017).

Assessment

Students’ achievements may be misidentified if their pathways of learning differ from that expected in the learning progression (e.g., Shavelson and Kurpius, 2012). Such interpretations, if used formatively, may result in students receiving inappropriate instruction. As a simple example, suppose that, based on prior learning and/or current circumstances, a student’s pathway should be “out of order” (e.g., A, C, B, D instead of A, B, C, D). Formatively, if the student’s responses to assessment tasks indicate mastery of component C, a teacher might assume that the student needs support to move from C to D. However, the student may struggle if that instruction builds on component B, which the student has not yet learned (see Fig. 2). Summatively, student responses that indicate difficulty with component B might lead to an assumption that the student has only mastered component A, not recognizing achievement with respect to component C.

Current and future research to explore and address equity concerns with and through learning progressions

Most researchers acknowledge that there are likely multiple pathways through the learning landscape for a particular competency (e.g., Battista, 2011; Smith et al., 2006). At the same time, many learning progressions are represented as single pathways with fixed components. In the previous section, I discussed what we might miss when (and the potential impacts of) trying to represent learning this way. In this section, I explore the possibilities when researchers respond to diversity: of students, their learning contexts, and the way they learn and demonstrate competencies. I highlight promising work, using it as a springboard to look forward to expanding these efforts.

Fig. 2 River metaphor showing consequences of a mismatch between a student’s pathway for learning (ordering of components) and that assumed in a learning progression Note: The student’s expected pathway is represented by the thin dashed lines connecting stepping stones A, C, and B and the targeted competency (D). Instruction (indicated by the thick black lines) is expected to support the relatively small movement from C to D in the standard pathway, rather than the bigger jump necessitated by skipping over B in the student’s pathway.

Central to my call for future research is a need to understand the equity problem with learning progressions. The discussion above (Section **Equity critiques of learning progressions**) purposefully did not address the severity of divergence we might expect between a learning progression and students' competencies and learning. Across the work described in the sub-sections below, I ask the following overarching questions:

- When do patterns in students' competencies and learning represented in learning progressions seem widely applicable (generalizable across students and learning contexts)?
- When are students' competencies and learning not fully represented in learning progressions?
 - What divergences appear?
 - How significant are the divergences? For how many students?
 - Are there any patterns in the divergences (e.g., across types of learning progressions, subject areas, or groups of students)?

Better understanding of what is being eliminated when learning progressions illuminate common patterns is essential to moving forward to address potential equity concerns.

Diversity of learning contexts

As mentioned briefly above (Section **Generalizability**), one source of variation across learning progressions is the extent to which they are designed to be generalizable across contexts and populations. Increasingly, learning progression research attends to the environment in which learning is expected to occur.

Providing information about learning context

One way to begin exploring learning progressions' generalizability is to be more explicit about the contexts in which they were developed. For example, curricula and/or other instructional supports are an important form of contextualization of the learning environment. When learning progression development occurs in tandem with curriculum development and/or design work (e.g., [Fonger et al., 2018](#); [Lehrer et al., 2014](#)), descriptions of the curricular context usually accompany the learning progression. Specially designed curriculum is often needed for students to move through a learning progression (e.g., [Plummer and Maynard, 2014](#)). However, where status quo instruction is assumed, information is needed about what that entails, as "status quo" is context-dependent. A better understanding of the curricular and instructional context of a given learning progression is an important step toward being able to explore how much such contexts impact the learning progressions that are developed.

On a broad scale, there are important differences across countries in terms of standards, curriculum, and learning environments (e.g., [Kelly et al., 2020](#)), and research on learning progressions is being conducted in many countries. However, the resulting progressions are often presented as if they were universally applicable. In a rare example of cross-national work, [Yao et al. \(2017\)](#) refined a learning progression for energy developed in Germany ([Neumann et al., 2013](#)), using data from Chinese students; however, they did not treat discrepancies between the original learning progression and their new data as potentially revealing distinctive features of Chinese students' learning. Similarly, articles reporting data from multiple countries do not necessarily consider potential differences across the sample (e.g., [Lai et al., 2017](#); [Wilkins and Norton, 2018](#)).

However, some researchers have begun to acknowledge and investigate cross-national differences in student learning. For example, while not restricting their learning progression to the Chinese context in which it was developed, [Gao et al. \(2020\)](#) provided two explanations for why a Chinese learning progression for buoyancy might differ those developed in other contexts: the meaning of the word "buoyancy" in the Chinese language and the way buoyancy is presented in Chinese textbooks (in terms of force). Such targeted descriptions might serve as a step toward more explicitly cross-national work, for example, comparison between learning progressions for Chinese students and learning progressions for students who learn buoyancy in terms of a property (density) of the object. There are already a few examples of such cross-national work in the literature, such as [Jin et al.'s \(2009\)](#) and [Liu and Tang's \(2004\)](#) investigations of differences between students in China and in the United States and in Canada, respectively.

Like [Confrey \(2019\)](#), I see a need for additional cross-cultural work to investigate how differences in cultural context (e.g., country) impact different types of learning progressions. For some competencies, multiple learning progressions have been developed, sometimes in different countries (see [Table 2](#)). To what extent do differences reflect different ways of developing the learning progressions vs. differences in the cultural contexts in which they were developed? Researchers might investigate similarities and differences when a common learning progression is modified in response to evidence collected in different countries (or other types of contexts). At the country level, it would be particularly important to involve researchers from lower income countries, as learning progression research to date has been conducted in higher income countries: those classified as "high income" or "upper middle income" by [The World Bank \(2021\)](#).

Developing context-specific learning progressions

In the previous sub-section, I described aspects of the learning environment (curriculum/instruction and national context) that directly impact what happens in the classroom. However, learning is also influenced by the experiences and other resources students bring to the classroom, as well as by their communities. Here, I see a special role for localized learning progressions. For example, [Ladachart et al.'s \(2020\)](#) highly place-based learning progression describes students' explanations for haze pollution, recognizing the importance of haze pollution in northern Thailand and students' experiential knowledge of this phenomenon. Learning

progressions like this are purposefully not generalizable. However, deep attention to place and place-based learning can shed light on the ways that learning progressions may be influenced by place.

Some researchers have suggested that learning progressions are intended to be broad frameworks that teachers will adapt to their own contexts (e.g., [Lehrer and Schauble, 2015](#)). Yet research is needed to explore how teachers adapt learning progressions in this way. Although [Furtak and Heredia \(2014\)](#) explored how teachers in one school took up a learning progression developed by teachers in another school, they did not explore/report adaptations. Systematic exploration of teachers' adaptations in different contexts and with different students would also help to characterize the extent and nature of context-based variation in learning progressions. In addition to individual variations (discussed below in Section [Student diversity](#)), the students in a class impact the instructional environment and, thus, are an important consideration in instructional context. As those "on the ground," teachers may be best positioned to respond to this diversity by identifying ways that their students' learning differs from what is represented in a learning progression.

Student diversity

In learning progression research, it is typical to reduce empirical evidence such that differences between students are smoothed away (e.g., [Battista, 2011](#); [Pierson et al., 2019](#)) and patterns of competencies not reflective of the group as a whole are considered noise or "misfit." When collecting evidence to validate and/or refine a learning progression, researchers attend to variation in their data; however, this variation is typically used to make revisions to capture common ideas not already represented in the learning progression (e.g., [Castro-Faix et al., 2021](#)), rather to describe less common alternatives in an expanded version of the learning progression. Therefore, while such attention reflects an important step, I echo the call from [Hammer and Sikorski \(2015\)](#) for "approaches to research that can capture and consider idiosyncrasy, not as statistical noise to eliminate but as part of the phenomena of interest" (p. 429). This will require greater attention to individual students, particularly those from marginalized groups, as more than "misfit" to statistical models. In the sub-sections below, I describe and call for work to explore, represent, and respond to student diversity.

Exploring student diversity

Although curriculum development-based design work often produces a single learning progression, these approaches include detailed engagement with individual students' competencies over time. As such, they are well-positioned to contribute rich descriptions of how individual students engage with the curriculum and make progress with respect to the learning progression. As [Alonzo and Elby \(2019\)](#) suggest, learning progressions (as imperfect models) could be used as springboards for teachers' inquiry. Collectively, this work could yield important insights about alternative learning progression components and pathways.

Detailed qualitative work could be complemented by promising new quantitative approaches to explore diversity in students' learning. Cognitive Diagnostic Models have the potential to generate multiple pathways during learning progression development and validation. For example, [Gao et al. \(2021\)](#) used latent class analyses and the rule space model to identify multiple pathways (i.e., ordering of learning progression components) that students might take in learning a competency. In a more novel approach, [Chiu and Wu \(2013\)](#) have used a classification method from biology (*cladistics* or *phylogenetic classification*) to create a learning progression in the form of a *conceptual evolution tree* (CET). Instead of representing the evolution of organisms, the CET shows "evolutionary pathways for the development of mental models" (p. 375).

Additional research (using these and other approaches) is needed to attend to and document diversity in students' competencies and learning. This is important for characterizing the different ways that learning progressions might fail to capture students' competencies and learning, and for producing learning progressions that exclude fewer students.

Work with marginalized populations

While there are many reasons students' learning might differ from what is depicted in a learning progression, equity concerns demand that we pay particular attention to students from marginalized groups. Learning progressions intended to be "universal" are most likely to be applicable to students who are not marginalized in their particular contexts (e.g., ethnically/racially part of a dominant group, fluent in the language of instruction and assessment, having no disabilities, having medium to high socioeconomic status). Indeed, most learning progression research has been conducted with such students (e.g., [Delgado and Morton, 2012](#); [Williams, 2018](#); [Zahner and Wynn, 2021](#)). There are, however, exceptions, as described below.

Some researchers have purposefully developed learning progressions through work with marginalized students (e.g., [Taylor and Brand, 2021](#)); others have sought to include these students, along with others, in their studies (e.g., [Delgado and Morton, 2012](#); [Songer et al., 2009](#)). The latter type of work has allowed researchers to make comparisons between sub-groups, such as students from urban vs. rural schools or children with different ethnic/racial backgrounds, based on performance relative to a learning progression (e.g., [Yao et al., 2017](#)) and/or growth using learning progression-aligned curriculum and instruction (e.g., [Clements and Sarama, 2008](#); [Delgado and Morton, 2012](#)). However, there have been few efforts to investigate whether a learning progression differs between groups of students. Additional work is needed to explore not just how much (relative to a learning progression) students have learned, but how the components and pathway of a learning progression might differ for marginalized students.

Recent work has also explored learning progressions for students with particular learning needs. [Bailey and Heritage \(2014\)](#) developed a learning progression for emergent bilingual learners. The learning progression describes the way these students learn language, both for use in its own right and to support the learning of other content. Similarly, [Kamei and Pavlovic \(2021\)](#) and

Strickland (2018) report work on learning progressions describing foundational competencies required for students with intellectual disabilities, developmental disabilities, and/or autism spectrum disorder to “access the general curriculum” (Kamei and Pavlovic, 2021, p. 2). Further work is needed to explore other prerequisite competencies. Work is also needed to explore how these students draw on prerequisite competencies for further learning, as it is likely that the learning pathways for these students differ substantially from those developed from and for their mainstream counterparts.

Representing diversity

As researchers have grappled with the complexity of representing student learning, representations have been generated to express that students’ learning is not as simple as portrayed in a series of linear levels. Expanding from the portrayal of a single, linear pathway, researchers in the Teach to One project represented components of a learning progression as connected by a wide array of possible pathways (Achieve, 2015), and Confrey et al. (2017b) characterize student thinking like a climbing wall, where multiple handholds can be used to reach the top (rather than like a ladder, where there is a single sequence of rungs). Sevan and Talanquer (2014) use a potential energy surface to represent the conceptual landscape of a learning progression; they identify regions of relative stability (i.e., components) but do not arrange these in a sequence or pathway. I encourage both further work of this type and representations that might capture greater diversity in the components of a learning progression and not just flexibility in the pathway through those components.

Responding to diversity

In addition to documenting variation in students’ competencies and learning, it is important to document how this variation plays out in the classroom and other contexts (e.g., large-scale assessment) and, more broadly, how the use of learning progressions impacts marginalized students. For example, a teacher in Myers (2015) used a learning progression to justify deficit views of students. However, Suh et al. (2020, p. 229) found that learning progression-based lesson study “facilitated ... equitable access to instruction” and asset-based views of students’ thinking, and Myers et al. (2015) have developed a promising framework for how learning progression-based instruction could promote equity. Their framework could serve as a strong foundation for further research investigating how teachers use learning progressions in practice and how their use of these tools can be made more equitable. For example, Bernardo (2017) started to bring the learning progression construct into dialog with culturally responsive teaching. As another example, Graf et al. (2021) are developing a learning progression with two strands aligned with curriculum modules from the Algebra Project (Silva et al., 1990), which is designed to support students from historically marginalized communities. Further research could explore questions such as: What does it look like for a learning progression to be used in the context of culturally responsive pedagogy? Can learning progressions (especially those that acknowledge students’ diversity) be used to support teachers in noticing all students’ competencies, not just those represented in the learning progression? What support do teachers need to use learning progressions in equitable ways?

Conclusion

Learning progressions research has flourished over the past two decades, with a plethora of research to develop, validate, and study the use of learning progressions across grade levels, subject areas, and countries. These learning progressions represent diversity in terms of the type of competency they describe, the nature of their components, their emphasis on ordering or pathways for learning, their generalizability, and their grain size.

The good news is that learning progressions are beginning to fulfill their envisioned promise to inform standards, curriculum, instruction, formative and summative assessment, and teacher learning. The bad news is that there is a potential for these uses to exacerbate, rather than ameliorate, educational inequities. Work to address potential equity problems will take coordinated effort. Answers to the questions posed at the beginning of the **Current and future research to explore and address equity concerns with and through learning progressions** section will require researchers to work together to study variation in learning progressions across contexts and groups of students, attending to unique characteristics of teaching and learning in each case and to the nuanced ways that students’ learning may differ from that depicted in a “standard” learning progression. There is significant work being undertaken on learning progressions. This work could be even more powerful, and have less inequitable consequences, if researchers can find ways to coordinate and attend more closely to the contexts of their work.

Introduction

Developmental and educational psychology are optimistic sciences. That optimism was captured in an early vision for the aim of developmental science which was to describe, explain and optimize intraindividual change and of interindividual differences in that change (Baltes et al., 1977). The assumption was that if we could get the descriptions right, and had robust explanations, then we would be in the position to optimize. The focus for Baltes et al. (1977) was development, but the same logic has been present for learning. However, it turns out that the sequence from description to optimization is not as linear as suggested, and the third part, which is the focus of this chapter on optimizing learning, is nowhere near as inevitable or easily achievable as implied.

The reason for having a more cautious optimism comes from knowing much more about the phenomena of learning than we did in the 1970s. We know much more about the proximal and distal conditions that affect learning, we know much more about the embedded systems in which a learner learns, and we know much more about the complexity of trying to change conditions and systems to optimize.

The complexity is captured in another programmatic statement which rejects the idea that we can discover “what works” in some universal and unqualified sense. In recognition of the variability, contextual adaptations and inconsistency in our attempts to optimize, especially when the focus is wide impact, the proposal is that we need to know what works for whom, under what conditions, and at scale (Bryk et al., 2015).

Baltes et al. (1977) were concerned with optimizing development across socialization settings. In this chapter, the focus is optimizing learning specifically in educational contexts. The concept of optimization is elaborated through the following discussion, but a preliminary definition is suggested here. Optimization means enabling what is valued educationally to be learned effectively, considered against five very closely related criteria. These are the robustness of learning; its transferability; the fluency and accuracy of that learning; its generalizability to abstracted principles and concepts; and the enhancement of further development through what is learned (McNaughton, 2018). The last criterion requires a horizon which marks having successfully optimized. Knowing what counts as success is especially significant for learners whose progress is lower than expected, or who have traditionally not been well served by schooling.

The present discussion of optimization adopts a systems framework for thinking about optimization. Much is known about specific variables which can impact on the individual learning, and especially when conditions are controlled in experimental analyses. For example, the properties of effective feedback, or the role of deliberate practice and opportunities to learn, have been described and explained in detail (Ericsson, 2006; Hattie and Timperley, 2007). But the more pressing questions, the ones we have yet to have definitive answers for, are more systemic and are more in keeping with Bryk et al.’s (2015) proposal.

There are two questions in particular which this chapter addresses. They are how to optimize at scale, and how to mitigate the risks. The former focuses on challenges in instructional designs to optimize learning at scale, and the latter on the seemingly intractable problems of optimization for all, conceived here as risks. To aid clarity, the discussion follows the Baltes et al. (1977) logic: describing the issues to do with optimizing, explaining them, and then considering what it would take to optimize learning.

Description: limited optimization is typical

Our attempts at optimization are hardly optimal: the current picture is one of variability in outcomes when optimizing at scale and limited sustainability over time. Optimal conditions and outcomes prove hard to replicate beyond initial experimental demonstrations (Kim, 2019).

The reasons for this description of the current state are illustrated in recent evaluation studies of Reading Recovery, an effective early intervention program accelerating literacy learning for those not making appropriate progress. Despite finding an overall strong effect size on a range of literacy outcome measures (a median effect size of 0.7), the school to school variation was substantial, varying from negative effect sizes, meaning intervention children in that site actually got worse than their control group peers, to effect sizes greater than +2.0, a positive impact almost unheard of in social science research interventions (May et al., 2013, 2016).

The variation was attributable to aspects of teaching termed “instructional strength,” reflecting the individual Reading Recovery teacher’s expertise with the instructional procedures. But it was also attributable at the school level to the degree to which the Reading Recovery teacher was well integrated into the school community and received endorsement by leaders. Further, at a district level, the constraints and enablers were about administrative support, in the forms of political recognition and funding, and this support needed to be ongoing. Finally, a constraint on implementation at a district level was turnover in the administrators. A follow up study replicated the primary finding of overall large effects on immediate outcomes, but also found very limited sustainability of achievement gains (May et al., 2022). This adds to the picture of variability, given that studies in other jurisdictions have detected long term gains (Appleton-Dyer et al. (2019)).

This pattern of variability in programs when implemented at scale is not limited to Reading Recovery or literacy; it is universal. It is found across many domains (Hill and Erickson, 2019; Kim, 2019) and across ages, from pre-K programs focused on self-regulation (Nesbitt and Farran, 2021) through to learning social and emotional skills and anti-bullying programs in secondary schools (Yeager et al. (2015)). More than this, variability is inherent in “business as usual” too, the everyday attempts to optimize learning; at every level of education; from granular to macro units of analysis (McNaughton, 2011); within classrooms and between classrooms; within schools and between schools; within and between clusters of school and districts; and within and between countries.

Sustaining the changes needed to optimize learning also has proven to be difficult as May et al. (2022) found, and not only at the individual student level. Schools that successfully implement reforms and improve achievement find it difficult to sustain them in the face of competing priorities, changing demands, changing student demographics and teacher and administrator turnover (Datonow, 2005).

The issue of sustainability of the conditions for optimizing learning when the unit of analysis is the school or a wider grouping of schools is a temporal one. The changes are hard to maintain over time for those involved. However, there is a second sense of sustainability when the unit of analysis is the individual’s learning. At this level it is a question of ongoing learning, the developmental significance of what is learned and what needs to be learned over time. In this sense what is optimized at one point is a condition for ongoing learning. The risk is that what is learned may not be optimal or as developmentally progressive as it could be for priming further learning and longer-term outcomes. This issue is readily apparent in core subjects such as literacy and numeracy learning.

Dual pathway models of early literacy learning identify two developing strands (Paris, 2005): one set of “constrained” knowledge and skills (e.g., phonological knowledge and alphabet knowledge), and a second set of “unconstrained” knowledge and skills (e.g., lexical knowledge and textual knowledge). They have different trajectories of development. The constrained set is learned faster and generally knowledge acquisition is completed early. The development of unconstrained skills is more gradual and open ended. Development of text reading for meaning is dependent on both sets being learned. But ongoing development of the unconstrained set is dependent on the how effectively the constrained set is learned, judged against the criteria noted earlier. In this sense, the constrained set are causal, they are building blocks which are necessary, but not sufficient, for development to proceed. The point for optimization is that optimizing which only focuses on the constrained skills, meets the necessary conditions for four of the criteria (robustness, transferability, fluency and accuracy, and in a principled way) but may not be sufficient for ongoing development. Indeed, a primary focus in the early years on the constrained skills risks opportunity costs for the learner and slowing development, by reducing opportunities to learn the unconstrained set (McNaughton, 2018). Meeting the final criterion of sustainability when considered as learning being developmentally progressive, is dependent on other learning being in place concurrently and consequentially.

Explanation: the limits to optimizing

Following the Baltes et al. (1977) sequence, this description of optimization as often variable at scale and over time requires explaining there are four major explanations for why we are not good at optimizing learning.

Fidelity to designs

The usual explanation for programmatic interventions being variable, which is also applicable to everyday teaching, focuses on the degree of specification or prescription in, and adherence to, the program design, curricula, syllabi, or lesson plans. This is treatment

fidelity or integrity. Fidelity to the “treatment” design is an established problem in the implementation of educational programs, and one of the major sources of influences on treatment effects (Hill and Erickson, 2019; Schochet et al., 2014; Coalition4evidence, 2013). Programs are hard to put in place reliably if the criterion is being consistent with the original program design. Durlak and DuPre (2008) reviewed 500 health and education programs for children and adolescents in studies from 1976 to 2006. There were generally low levels of compliance to the program design. They identified a long list of 23 contextual factors that influenced the fidelity of implementation.

The local context creates special circumstances for putting a program in place (Schochet et al., 2014). The 23 contextual features identified by Durlak and DuPre (2008) are illustrative of the sources identified for the Reading Recovery example. They include leadership, teacher skills and knowledge, resources, and the presence of other programs. When taking programs to scale, or when they are embedded as business as usual, the sources also include differences between the original demonstrations under carefully controlled and well-resourced conditions, and the conditions faced in wider implementation and in everyday settings when the original conditions such as researcher input, funding and participant buy-in are not present.

Adaptation on the ground

It matters whether the evidence-based instructional processes are followed with integrity. But there is a second explanation for the variability in optimizing. Teachers in the local context adapt. Even in the most prescriptive programs which attempt to control variation by close specification, it is present (Bryk et al., 2015; Hill and Erickson, 2019). The variability on the ground is not just through a failure to follow the design.

To adapt and innovate is in the nature of complex human activity. Teachers use their tools and deploy instruction in ways that reflect aspects of their expert knowledge, skills, values and goals. Some variability comes about because educators in local systems will, to a greater or lesser extent, modify and adapt the instructional designs and practices specified by their curricula and programs. Being an expert within a community of experts, with one’s own motivations, values and levels of expertise, mean practices are dynamic and sensitive; they change through responses to new conditions and knowledge.

Hill and Erickson, 2019 point out that studies of adaptation of interventions are rare. Some of the adaptations will be detrimental and undermine effectiveness and compromise optimization. Some will be progressive and contribute to optimization. Some of that adaptation may reflect the need to contextualize the generally effective instructional designs to the local circumstances. Some variability will reflect effective innovation. Each of these underline the need to know what works for whom under known conditions at scale, leading to much better nuanced specifications for the instructional design. Contemporary descriptions of effective teaching use the model of adaptive expertise to explain how optimization in the moment-by-moment implementation of curricula and pedagogy depends on the adaptations that skillful professionals make (Darling-Hammond and Bransford, 2005).

The conundrum that we face in educational systems when optimizing at scale is where to set the balance (McNaughton, 2021). It is between enough prescription to guarantee consistency in application of what is known to be effective across contexts, but “loose” enough in the specifications to enable the moment-by-moment adaptations and the progressive forms of innovation. Solving that balance problem is crucially dependant on enabling conditions such as those noted in the Reading Recovery example: the training of the teacher, and supporting conditions within and across sites.

Resourcing for sustainable change

The role of enabling conditions for optimizing leads to the third explanation—the resourcing of teaching, such as physical or social resources, strong leadership and professional development for teaching and the educational resources available to the schools and the communities that schools serve.

An example of realizing how optimization depends on enabling conditions (and not just the curriculum and pedagogical specifications) comes from the KEEP research with schools in the Kamehameha district in Hawai’i in the 1970s. The intervention focused on building higher achievement levels in reading than the typical low levels for indigenous Hawaiian students (Tharp et al., 2000). It was very successful and pronounced gains in reading achievement occurred, both in the original schools and in scaling up to multicultural public schools over an 18 year period.

But in 1997 it was formally terminated, and the researchers identified two issues. One was too rapid expansion, with consequent diminution of resources and a shift away from the original instructional design. The second was the intervention focus, which was based on culturally responsive reading instruction, but designed and implemented only in the early grades. It was not a whole school approach, addressing the issues of sustainability and developmental significance. Like other interventions based on culturally responsive pedagogy, it matters what the school leadership provides and it matters how the pedagogy is applied across year levels and subject domains. More than this, it matters that the resources to support these continue to be available.

More to know in instructional science

The fourth explanation is a truism: we always will need to know more. One example of this can be found in the idea of “instructional risk” (McNaughton, 2018). This proposes that all instruction carries risks to being effective. Our knowledge of how to optimize learning currently is limited because of not having the best evidence for how to mitigate the risks. We are still unraveling how the risks emerge and how to mitigate them.

Instructional risks come about in a number of ways. One is through limited specification of the components needed for learning. An example is how inquiry and discovery approaches in science and mathematics are problematic without teacher mediation. Guided inquiry or discovery is superior to inquiry alone and more direct didactic instruction (Alfieri et al., 2011; Furtak et al., 2012). Another example occurs across a range of applications of strategy instruction where the focus of instruction shifts to the strategies themselves and formulaic teaching of these, which has been called the risk of “proceduralisation” (Wilkinson and Son, 2010). Yet another example is how to mitigate the default to classroom discourse comprised of limited question and answer sequences, and reliably increase extended discourse which triggers more epistemic talk from the learner (Lefstein et al., 2021).

There is more to know about how to identify and incorporate cultural practices in optimizing the learning for culturally diverse children. For example, the qualities of complex dialogic exchanges in classrooms can be conceived in ways that reflect cultural meanings for students from Pacific nations, leading to more effective professional development to change classroom practices (Oldehaver, 2018). Oldehaver’s framing of dialogic turns using cultural meanings follows the instructional design of “cultural modeling” in English Language Arts (Lee, 2007). Effective teaching needs to be able to activate the learner’s existing knowledge and skill embedded in cultural practices and make explicit how to transfer from their cultural repertoires to using similar practices on unknown and canonical texts in school curricula. Among the questions which challenge systems to be more consistent at scale is what do all teachers need to know and how are they best prepared to engage with learners in the ways Lee and Oldehaver and others have described.

What is needed for successful optimization

Resolving the above issues requires greater clarity about what counts as successfully optimizing. It also requires a research and development capability based on the science of implementation. This is needed to meet the Bryk et al. (2015) challenge to nuance our understandings for different contexts, conditions, groups of students and across time.

Clarity about what counts as success

Optimizing learning has three properties, the outcomes are stochastic, the criteria are dynamic, and the criteria are values based. Each of these properties is present in how interventions at scale can view success for low progress, low achieving groups traditionally not well served by schools. In this illustrative case, the interplay between rate of learning and level of achievement of what has been learned is key to what schools can do to address the disparities associated with poverty and marginalization.

Given differential rates of progress emerging in the early years on school related measures of learning such as school readiness, optimization through schooling can be defined as *accelerated learning* such that students; (a) make more than the expected rate of rates of progress, and (b) as a group come to approximate expected distributions of achievement. For groups traditionally not well served by schooling, the goal is to accelerate sufficiently to match the distribution of all students in the defined “universe” of students. These are usually the population on which standardized assessments are based, with the probability of being in the top, middle and lower bands of that distribution being the same as the appropriate population at scale.

Values are central to such a definition of success (Kyriakides and Creemers, 2011). The matched distribution criterion is based on a value of equitable outcomes, as distinct from equitable input or opportunities. Because curricula are templates for what a society values in its citizens, the success criterion also is by definition values based. Whether the curriculum values themselves are equitable is an additional question, and part of the conditions for enabling optimization to occur.

In this example, the phenomena of success are probabilistic in the sense that a distribution is expected. But the outcomes are probabilistic in a second sense that both the processes and outcomes are variable, and as will be argued below, there should be some, tolerable levels of variability. Finally, the criterion is changeable as new curricula and new measures such as discussed below for critical literacy come to be adopted.

Optimizing in business as usual and within planned interventions has to solve a classic balance problem related to success criteria and the variability inherent in attempts to optimize. It is getting the balance right between prescription to ensure consistency through fidelity to effective instructional design, and enabling local capability to innovate.

In another form it is also the degrees of freedom needed to adapt what is generic to the particular needs of the individual learner. This is the challenge of being an “adaptive expert” (Darling-Hammond and Bransford, 2005). Being both expert and adaptive requires something akin to jazz extemporization, or what theories of social structures also call “deep improvisation” (Tilly, 1998). The capability to extemporize, to be adaptive, arises from high levels of local knowledge and moderate levels of scripting.

Solving the variability conundrum requires a balance between prescription and opportunity to innovate. The three properties of being stochastic, dynamic and values based suggest that the way to address the variability inherent in our attempts to optimize is to set tolerance levels for variability. Rather than having a fixed binary view of having optimized, interventions or more broadly, educational sites, could set shared targets for tolerance levels for variability. The desired net effect of setting these should be to increase consistency without reducing innovation.

A science of optimization

The implementation science position taken by Bryk et al. (2015) with which this chapter started, sets a direction for optimization research. Considering what works for whom under what conditions and at scale, and is sustainable over time, directs attention to understanding interventions at scale as a scientific problem in itself. This is also the case for optimization, solving the variability issues requires better science.

Implementation science and the wider agenda for design-based research (Snow, 2015) provides a methodology for optimization research. Using this methodology, variability can be a source of evidence for local innovation and the solving of educational challenges. Capitalizing on progressive adaptations adds power to the design of interventions. Even though teachers' knowledge of the innovative practices may be incipient and "pre scientific" (Vygotsky, 1978), progressive innovations are potentially able to be disciplined by research partners through technical language, testing and by being made explicit. The core premise here is that difficulties in problems of scaling and sustainability can be better solved with elements of local solutions in the design. This is because local solutions are likely to be more relevant and acceptable to others in that context, and also more contextually valid in that they are reflective of conditions in the local context not appreciated by outsiders.

This requires a different view of treatment integrity as not just prescription with adherence to the program design. We should see it as building high levels of capability to act flexibly and adaptively as "adaptive experts" based on knowing and acting with the core components of the program design, within a community of experts. This capability is dependent on a moderate level of prescription rather than a high level. Low prescription can provide opportunity for capability building but increases the likelihood of inequitable variability below tolerance limits. High prescription is antithetical to longer term capability building. It is also dependent on the embedded discourse and pedagogically productive talk that occurs in the community of practice to which teachers belong (Lefstein et al., 2021).

Clearly, building the capability to optimize is not just a function of setting a "moderate" level of prescription in the instructional design, be it from an intervention program or in business as usual. It is dependent on the preparation and consequent proficiency levels of teachers. It is dependent on ongoing professional development. It is dependent on the conditions and contexts identified in the Reading Recovery evaluation and the summary of context effects on implementation fidelity identified by Durlak and Dupree (2008).

Mitigating risks to optimizing

Trying to optimize comes with risks and potential untoward side effects. But these can be mitigated. Some of these have been noted already, but three closely related risks to successful optimizing are particularly problematic: inequitable resourcing and outcomes, narrowing the educational benefit, and the risk of cultural blindness. The principles for mitigating these risks include differentiating optimization, setting a wide focus for optimizing, and preserving identity language and culture.

Differentiated optimization

Unfortunately, the default condition in instruction, and at the level of interventions and business as usual in schools is rich get richer/poor get poorer effects, or "Matthew Effects" (McNaughton, 2011; Stanovich, 1986). The risk is some may benefit more from optimizing than others. The phenomena take two forms. A "match" form occurs where those with more relevant and more articulated knowledge and skills can make greater sense or use of conditions that are universally provided. In the beginning stages of literacy learning at school, those children already with advanced literacy skills and knowledge can make greater progress from the instruction provided and thereby gain faster access to more and more complex activities for learning, such as more complex texts for reading which expose them to more complex text features including vocabulary. And learning these increases skills levels and access further.

There is also a systemic form where levers such as funding or the provision of high quality courses and highly qualified teachers are systematically different for schools serving different communities. Both phenomena are ubiquitous over a wide range of structural features and activities in education (Ceci and Papierno, 2005), both in universal provision as well as targeted interventions.

Mitigating the risk is a matter of how well differentiated and fit-for-purpose interventions and everyday instruction are. The need for differential targeting in everyday provisions is illustrated by the "summer slide" patterns, where progress in reading, writing and maths during the summer break in schooling tends to be slower for students from communities with less access to the social, cultural and financial capital that make a difference to school based learning. These are often children from low SES and from marginalized communities. Universal conditions during school time are not sufficient to offset the out-of-school conditions and early differences in school-related learning tend to persist or grow across time at school. Several optimization responses are possible ranging from increasing the "dosage" of effective instruction for learners at risk of Matthew effects, through to changing the outside conditions by providing resources for school-related learning such as sending books home (Kim and Quinn, 2013).

Focusing on higher order and interdependent skills

A more general challenge to being successful facing many school systems currently, is whether we optimize learning across all the domains we value or have come to value—not only the usual core subjects of reading writing and mathematics, but also the higher order, so-called, 21st century skills. These are commonly divided into three categories or clusters. Two of these clusters, which have been called non-cognitive skills (Kautz et al., 2014), consist of interpersonal (e.g., perspective taking, empathy and prosocial skills) and intrapersonal (e.g., self-regulation and persistence) skills. Despite the categorization both clearly include cognitive elements. For example, regulation of attentional, emotional and behavioral actions and guiding or making reflective decisions about learning rely on strategies of prospection and metacognition deployed in recursive situation–attention–appraisal–response sequences (Duckworth et al., 2014). The third cluster focuses specifically on the cognitive areas of reasoning and analysis (e.g., critical thinking, critical literacy, and critical reasoning/argumentation).

The answer to the question of whether we attempt to optimize learning across valued domains as much as we should is—“not enough.” Take for example, critical literacy, which is a focus in many educational systems and is now a core part of international assessments (www.oecd.org/pisa/test). Critical literacy (“media literacy,” “epistemic vigilance”) skills are increasingly recognized as important for resilience and more generally as core citizenship skills. These do not just sum to a predisposition to questioning things or the status quo, but include cognitive skills of “criticality” (e.g., critical evaluation, reasoned judgments, identifying accuracy and credibility of information).

Access to information online, online communities and social media markedly increase the potential for mis-, dis- and mal-information, manipulation and prejudice. Risks to our valued outcomes for schooling come from how opinions can be manipulated with the rapid and extensive access to information and with the use of smart social-media platforms. Self-perpetuating and reinforcing systems of knowledge are created whereby the various degraded information sources, inaccuracies or untruths are taken as truths through the repetition and support within the network (Supovitz et al. (2017). The potential consequence is the uncritical adoption of positions on political and other issues, and uninformed resistance to alternative views.

Despite the curriculum focus and the increased need, students’ ability to reason effectively, navigate sources of information confidently, and engage critically with the systems of knowledge in content areas, are not taught well, across schooling and even at college level (Fraillon et al., 2018; McGrew et al., 2017).

Optimization will need to guarantee transfer from classroom to everyday use with these problematic information sources. Currently, the consensus is that a “mixed” approach involving explicit instruction in thinking critically embedded in major subjects, coupled with some dedicated course work focused on the critical literacy (media literacy) skills, such as in civics or philosophy courses, likely work best for transfer (Horn and Veermans, 2019). In addition to embedded and deliberate forms of instruction, communities of practice at a classroom and school level, which feature caring teacher and student relationships, clear norms, expectations and practices, create the effective conditions needed for the acquisition of these skills (Abrami et al., 2015). As with the opening example of Reading Recovery, conditions at a whole school level, as well as specific instructional moves need to be in place for optimizing.

These different domains of learning valued by schooling systems have interdependencies (Resnick et al., 2015). The reciprocal relationships between academic achievement and well-being for example are clear. Interpersonal skills (e.g., sociability) and intrapersonal skills (e.g., self-regulation) predict long-term educational and post-schooling success (Kautz et al., 2014). More specifically, levels of self-control and self-regulation are consistently associated with achievement outcomes (Duckworth et al., 2014; Zimmerman, 2008) and these skills and their relationships with cognitive development are identifiable early. For example, relationships are found between self-regulation, empathy and prosocial behavior, with emergent literacy and numeracy at the transition to school (OECD, 2020).

A research agenda for optimization includes designing for these interdependencies as a means of adding value to outcomes, but also because building the interdependencies is necessary for citizenship skills and resilience. The need and opportunities to optimize the learning of critical literacy and social and emotional skills has increased with the rapid expansion and extension of digital environments creating ubiquitous access and use by learners.

Digital worlds add urgency because social media increases threats to social and emotional development (Courage et al., 2015; Reid Chassiakos et al., 2016). Users of social media tend to have reduced capacity to judge the appropriateness of their own behavior and new vehicles for bullying are created (Aiken, 2016; Foody Samara Carlbring, 2015; Gardella et al., 2017).

An example of building on interdependencies is the instructional design for argumentation or collaborative reasoning. The designs require critical thinking skills as well as perspective taking and aspects of cognitive and emotional empathy (Kuhn, 2005; Rapanta et al., 2013). In well-designed interventions with classroom communities, skills are found to be generalizable across curriculum areas, from oral to written modes and from peer to peer (e.g., Reznitskaya et al., 2001; Kuhn, 2005; Rapanta et al., 2013).

However, as with critical literacy, low levels of argumentation and weak skills generally have been reported across grade levels and disciplines (Litma and Greenleaf, 2017; Kuhn, 2005), largely attributed to the absence of explicit instructional designs and deliberate socialization at class and school levels. The issue once again is how to take to scale the designs known to be effective. In addition to the specific instructional events, it means overarching enablers such as curriculum designations and widely socialized values such as those present in Finland’s anti-fake news campaign and revision to their critical thinking curriculum (Horn and Veermans, 2019). It also means a widely available and equitable research and development capability to partner with schools to co-design classroom, school and district level conditions.

Recognizing the significance of identity, language and culture

One form of the differential impact that educational systems have is through their treatment of culturally diverse students. Mainstream systems, even those identified as a “high quality” system, can have near optimal outcomes for many but which undermine or exclude culturally based skills and practices of some. This is despite evidence about the significance of identity, language and culture in equitable educational success.

The evidence from specific frameworks to optimize learning for culturally diverse students such as cultural modeling (Lee, 2007), and more generally, culturally responsive pedagogy is that learning is more robust by creating instructional bridges for generalizable learning and through recursive impacts on self-efficacy and well-being for robust learning. The relationships are detectable from large-scale studies showing that within and between countries the learner’s sense of belonging and being respected predict achievement in reading literacy at 15 years (OECD, 2017).

Optimizing for culturally diverse students from marginalized communities can be seen as a special case of personalization of learning (Cazden, 2001). Optimizing for this at scale poses daunting challenges for jurisdictions to solve. Reiterating the implications made above, it includes patterns of recruitment and training in initial teacher education, as well as interventions which are inclusive and additive, rather than exclusive and subtractive.

Conclusion: is optimization a chimera?

These descriptions of the limitations of our attempts at optimizing might suggest that we should reject the idea as unattainable. Certainly, the idea that a state of having optimized can be derived from a process of describing and then explaining was naïve, given the features of processes and outcomes being probabilistic, the criteria for what counts as success being changeable, and our intentions being framed by values.

However, despite the caveats, there are clear directions current evidence indicates we can take. Two lessons in particular can be drawn from the explanations of optimizing. These are the need to be very clear about what counts as optimizing, and leveraging off the science of implementation to inform optimization: in different contexts and under different conditions, for different groups of students, and in ways that are sustainable.

Apprenticeship learning is a central macro-approach to how learning and teaching can take place, standing in contrast to schooling as the second central macro-approach (Eberle, 2018). In the apprenticeship learning approach, learning takes place in the real-life context in which the content to be learned is of immediate relevance. Learning is understood as developing expertise in practices relevant in the learner's current life and comes with engaging in these practices. Furthermore, learning takes place in a fully contextualized way, within the real-life context in which experienced practitioners carry out their activities, and learning goes alongside the regular flow of practices. In addition, apprenticeship learning is situated in a meaningful social context of practitioners, the so-called community of practice. Social relations in the community of practice usually can be characterized either as person-centered, defined by a close relationship between a guiding master and one or several apprentices, or as decentered, when the learner is more loosely related to the members of the community of practice (Nielsen, 2010). Apprenticeship learning is mostly applied to observable practices but can also be applied to cognitive skills.

This chapter first addresses the central characteristics of apprenticeship learning and contrasts them to the schooling approach as the second major macro-approach. Next, the roots and the development of the apprenticeship learning approach are described, on the one hand from a historical perspective, on the other hand from an educational research perspective. Then, two strands of research on apprenticeship learning are presented that take the learner perspective into account and provide insights into the mechanisms behind apprenticeship learning: apprenticeship learning in communities of practice, and a developmental perspective based on apprenticeship. In subsequent sections, the teaching/educational organization perspective is addressed. The common goal is to bring the apprenticeship learning and the schooling approaches together, looking first at the formal organizational perspective in vocational training, and next at an instructional design-approach that allows for combining both approaches in the classroom.

Characteristics of apprenticeship learning

Apprenticeship learning is a complex concept that comes in many different forms. A generally accepted definition does not exist as most concise definitions tend to focus on only some central characteristics of the concept but neglect others based on the purpose and context in which the definition is used. Starting with the relatively vague definition that apprenticeship learning is one of two major macro-approaches for the organization of teaching and learning, the characteristics of apprenticeship learning can best be understood by contrasting it to schooling as the second major macro-approach.

Apprenticeship learning is based on a "participation metaphor" of learning (Sfard, 1998). That is, learning is understood holistically as becoming a person who actively participates in a community of practice, knowledgeably performs relevant practices, and acts in accordance with the norms and values of this community. This idea of learning stands in contrast to the schooling approach that focuses primarily on the acquisition of explicit knowledge and the increase in a set of predefined skills. This core difference gives reason for further differences in how learning and teaching take place in the two approaches. These differences can be found in nine core aspects: the epistemic/functional context, the relevance of learning, the sequencing of learning tasks, the social context, the role of the expert, the responsibility for learning, the relationship between expert and learner, the learning content, and the central form of learning (Collins, 2015; Eberle, 2018).

Regarding the *epistemic/functional context*, apprenticeship learning takes place in a real situation when a real problem occurs or a real task is performed. This situation occurs naturally and learning is rather a side-effect, in contrast to schooling where artificial situations are created and specifically designed to foster learning. Apprenticeship learning is embedded in the same context in which the apprentices will still be when they have become experts; that is, learning and application are not separated in time and space but learning takes place during application. For example, a baker apprentice usually learns in the bakery, surrounded by experienced bakers and participates from the start in preparing bread that will be sold to customers. Consequently, what is learned in an apprenticeship context is of immediate *relevance* to performing a task or solving a problem. In the baker scenario, for example, the baker apprentice learns how to prepare a certain type of bread and how to treat the dough when the bread is needed. And when the dough does not rise as it is supposed to do, solutions for this problem needs to be found on the spot. The schooling approach, in contrast, aims at preparing learners for situations in a distant future.

This example also shows the difference between the two approaches regarding the *sequencing of learning tasks*. In the apprenticeship learning approach, learning opportunities emerge from the context and as part of the practices, either when incidents occur that provide a new situation in which learning is required or when the apprentice initiates specific learning situations to gain better understanding during regular practices. In general, learning tasks are primarily created from the bottom up and the central goal or outcome is very clear while learning about details follows the sequence of required activities toward the achievement of a goal. Apprentices learn by participating in the different tasks according to what is possible at their current state of expertise. For example, the baker apprentice may, in the beginning, do very simple tasks such as providing ingredients or cleaning the bakery, and only later do more complex activities such as preparing the dough and forming bread. In the schooling approach, in contrast, learning is structured top-down following a specifically designed learning sequence based on the structure of knowledge (e.g., going from one topic to the next, providing information chronologically) while possibilities for applying this knowledge later on are usually secondary.

In addition, the *social context* in apprenticeship learning is a real social context that existed before an apprentice entered the picture, and becoming a respected member of this social community is part of the apprenticeship learning experience. In opposition to this, the social context in schooling is created artificially with the best learning outcomes in mind, usually bringing together an expert and often a homogenous group of learners.

In both approaches, an expert has an important part, but the *role of the expert* differs. Following an apprenticeship learning approach, the expert is an experienced master in the practices and acts primarily as a coach during naturally occurring learning situations. The master's central task is, however, to perform the practices while the coaching role of the otherwise autonomously performing and self-regulated learning apprentice is secondary. In the schooling approach, the expert is usually a teacher who structures the learning experiences and designs the learning process.

Consequently, the *responsibility for the learning process* is very different for the two approaches. The teacher, on the one hand, is the central person who pre-structures and initiates learning processes. The master, on the other hand has a more reactive role. A master may notice learning affordances of the context and use this for an ad-hoc lesson, (e.g., when the bread is about to burn, the master baker may use the situation to explain to their apprentices the importance for setting a timer and that a certain smell indicates that the bread is ready). In many cases, the apprentices will be the ones to request teaching from the master, when they seek more information or guidance, and the master can react to these requests.

The *relationship between expert and learner* in the apprenticeship learning approach is, accordingly, relatively close and the master knows the individual strengths and weaknesses of the apprentices well. Apprenticeship learning also relies on many one-on-one interactions and the master is usually responsible for a very small group of apprentices. These aspects give the master room for individually tailored feedback and guidance that is in the zone of proximal development for each apprentice. Unlike masters, teachers can educate larger numbers of students at the same time but serving individual learners' needs is a challenge.

The *learning content*, for which apprenticeship learning is best suited, are observable practices. Schooling, in contrast, has its strength in academic skills that are "in the head" of people and largely unobservable. However, unobservable academic skills and practices can also be the content of apprenticeship learning but requires some specific methods (see cognitive apprenticeship below). The *central form of learning* is, therefore, observational learning and active doing in the apprenticeship approach, unlike the schooling approach, in which instruction and practice are the most dominant forms of learning.

Roots and developments of apprenticeship learning

Historical roots and development

Before industrialization, apprenticeship learning was the most common form of occupational learning. The term refers to a form of training agreement between a master and an apprentice regarding a craft, art, or trade and the earliest historical references of apprenticeship learning date back to the Babylonian age ([The Editors of Encyclopedia Britannica, 2020](#)). However, apprenticeship agreements often went much further than mere occupational training and were often described as part of or similar to an adoption in which the apprentice becomes, at least temporarily, a part of the master's family (e.g., [The Code of Hammurabi](#)). The reason for this is that many occupations require more than just the knowledge and skills to perform specific occupational activities but come with a specific lifestyle and values and are embedded in the larger society as well as in specific communities associated with the occupation. For example, being a baker requires not only knowledge about recipes and baking skills but also requires that the baker starts to prepare the dough very early in the morning, so the bread is ready when customers come to buy it for breakfast.

In medieval Europe, apprenticeship learning was organized in craft guilds. And although this learning was mostly applied in observable hands-on crafts and the acquisition of physical skills, predominantly cognitive occupations such as scientists or clerics also followed an apprenticeship approach ([The Editors of Encyclopedia Britannica, 2020](#)) of which elements are still visible today.

Alongside the apprenticeship approach, the schooling approach also has a long tradition but was used to provide training only for children of a small elite and only in cognitive domains. With the changed organization of work that came with the industrialization, and even more with the transition into a knowledge society, the schooling approach replaced the apprenticeship approach as the dominant way of training in many areas ([Nielsen, 2010](#)). However, as both approaches have distinct advantages that are missing when relying on only one of them, we increasingly see attempts to bring them together by bringing elements of apprenticeship learning into school or by combining apprenticeship learning and schooling in occupational learning.

Roots and development in educational research

In educational research, apprenticeship learning gained broader attention around the late 1980s. Researchers from multiple backgrounds started to look at aspects closely related to apprenticeship learning from different perspectives ([Nielsen, 2010](#)). Anthropologists contributed ethnographic studies on situated learning and learning as a social practice. Educational philosophers, cognitive scientists, and computer scientists explored situated cognition—how knowledge, and practices are represented in the human mind and how they can be simulated by technology—drawing conclusions for learning. Learning scientists, finally, explored ways to successfully implement elements of apprenticeship learning into classroom settings, drawing from Vygotsky's work on socio-cultural learning and Bandura's social learning theory.

Furthermore, in the upcoming branch of artificial intelligence, the term apprenticeship learning is used for describing a certain type of machine learning. Specifically, in this context, apprenticeship learning means that machines are trained by observing an expert model performing a task ([Abbeel and Ng, 2004](#)). This approach is especially helpful for complex learning tasks for which the desired outcome cannot easily be put into an algorithm.

Based on the different roots of research on apprenticeship learning, we can find different strands and perspectives on the topic. First, there is a research strand examining the learning process of apprenticeship learning. This research is predominantly conducted using ethnographic methodology. One part within this research strand investigates “classical” apprenticeship learning in communities of practice, looking mostly at newcomers in different contexts and analyzing the details of how they become recognized, knowledgeable, and skilled members. The other part of this research strand applies the concept of apprenticeship learning to child development, seeing the child as an apprentice in their surrounding world who increasingly learns to participate in everyday life while growing up. The second major research strand examines apprenticeship learning from a teaching perspective and how it can best be brought together with schooling. A sub-strand of this approach takes a macro-perspective on vocational education systems. Another sub-strand takes an instructional design perspective and explores ways of bringing elements of apprenticeship learning into classroom settings and applying the approach to mainly cognitive learning situations. This is called the cognitive apprenticeship approach.

Apprenticeship learning from the learning perspective

Apprenticeship learning in communities of practice

Apprenticeship learning is an inherently social approach to structure teaching and learning and the community of practice is the social and epistemic context in which it takes place. A community of practice is usually not externally designed but emerges on its own. The term “community of practice” has become widely known. It has even received attention beyond academia and has become popular in organizational contexts. This popularity has led to a still evolving definition of the term and lack of coherence in its use ([Lindkvist, 2005](#)). Nevertheless, several characteristics distinguish communities of practice from other social groups ([Barab and Duffy, 2000](#); [Barab et al., 2003](#)). The reason for forming the community is a common practice and/or a mutual enterprise shared by several people. To be successful in this enterprise, community members need each other; that is, mutual interdependence exists. Accordingly, the community creates opportunities for its members to interact with each other and allows all members, especially newcomers, to participate to some extent in the practices of the community. The diverse perspective that the members bring together, is valued as a core element of the community of practice, including minority perspectives. However, the community members have a certain amount of shared knowledge, values, and beliefs that holds the community together. These stem from a shared history over a significant part of the membership. The relationships among community members are considered as meaningful with a long-term perspective. Members of the community see value in it beyond the individual relationships but tend to care for the existence of the community in the long-term future, and, consequently, develop mechanisms to bring in new members, who at some point in time can take over the community.

The idea of communities of practice, and the apprenticeship learning process that takes place in them, dates back to [Lave and Wenger's \(1991\)](#) book in which they provide a variety of examples of apprenticeship learning situations, such as midwives in Yucatan, butchers in German butcher shops, and Alcoholics Anonymous. The authors define the apprenticeship learning process as legitimate peripheral participation in communities of practice. This emphasizes that, to increasingly become a member of the community, learners need legitimate access to the community, its practices and knowledge, and the interaction opportunities of the members. When legitimate access is granted, learners need opportunities to participate peripherally in the beginning and,

increasingly, opportunities for participation in more central aspects of the community's practices. Peripheral participation allows newcomers to actively participate already from the beginning and contribute to the community but also provide opportunities to listen and observe what more experienced members do and to get acquainted with the practices and values. With increasing understanding, knowledge, and skills, the former newcomer can take over more complex tasks. The "curriculum" of this learning starts with understanding the central result, such as delivering a healthy baby for midwives in Yucatan, and follows the necessary steps to achieve this goal with an increasingly active role in the process. The apprentices often work together with a master and other community members of varying experience levels, who can be observed and guide the learning process. How easy or hard becoming a members of the community of practice is depends on participation support structures used by the community, which enable legitimate peripheral participation (Eberle et al., 2014; Nistor, 2016).

The legitimate peripheral participation process during apprenticeship situations has been observed in various occupational contexts, such as police officers, nurses, psychiatrists and teachers (e.g., Lave and Wenger, 1991; Lambson, 2010). However, legitimate peripheral participation also takes place in contexts unrelated to occupational learning, such as for parents in home schooling communities (Safran, 2010) or in witch circles (Merriam et al., 2003).

Developmental perspective on apprenticeship learning

The concept of apprenticeship learning can also be applied to child development by seeing children as apprentices in their culture or as "universal" legitimate peripheral participants, who learn to use language, develop an understanding of the world, and ways to think, through interpersonal mechanisms (Rogoff, 1991; Rogoff et al., 2003). Building on Vygotsky's (1978) work on the zone of proximal development, children learn when being supported by more knowledgeable others through guided participation (Rogoff et al., 1993). Interaction with adults and peers can be seen as the driving factor for development and increasing participation in the world (Rogoff, 1991).

Ethnographic research in this field found that caregivers in highly industrialized cultures, in which the schooling approach is the major form of education, tend to adopt a more school-like approach early on in their interaction with toddlers. By contrast, caregivers in less industrialized cultures with primarily apprenticeship approaches to education show a more apprenticeship-oriented behavior toward toddlers. Each seeks to prepare children for their further education (Rogoff et al., 1993).

Similar to apprenticeship in occupational learning, the developmental apprenticeship approach sees the responsibility for initiating learning with the children instead of with the caregivers. Children peripherally participate in the everyday activities of their caregivers, such as performing household chores, and this context provides opportunities for learning. Children can observe what their caregivers do and caregivers guide children's observations and attention to the general context, often using few verbal instructions. Children can initiate further interaction around occurring activities or everyday objects they find interesting. Caregivers then react to children's interests and specifically show them how to do what they are interested in, and help them participate in the practices. This guided participation allows children to participate peripherally until they are able to do the activity without support. Caregivers with a predominantly schooling-oriented approach, in contrast, design specific learning situations outside of their own everyday activities. They also feel responsible for initiating learning situations instead of reacting to the children.

Apprenticeship learning from the teaching perspective

As the learning perspective shows, apprenticeship learning has several benefits that the schooling approach lacks. A central advantage of the apprenticeship learning approach is that instruction usually takes place when learners face an immediate need for new knowledge and are, therefore, willing to listen, observe, and learn, whereas the benefits for learning in the schooling approach are often more distal and abstract, making the maintenance of learners' motivation a challenge for teachers. Another advantage is that the learned knowledge can be immediately applied to a concrete problem when it is most helpful. The emphasis on the social context and the wholistic perspective on learning inherent in the apprenticeship learning approach is an urgently needed addition to the schooling approach. Schooling traditionally has focused on individual knowledge acquisition in a distinct domain and neglected social and affective aspects, as well as the importance of identity development. Two research strands explore how apprenticeship learning and schooling can best be brought together, the first taking a macro-institutional perspective on vocational education systems, the second taking a micro-instructional-design approach on how to implement aspects of apprenticeship learning in the classroom.

Apprenticeship learning in vocational training

In the context of vocational training, apprenticeship learning is one of the most common forms of work-based learning. It is often not clearly distinguished from related forms such as traineeship, on-the-job training, or internships. All of them are characterized as forms of learning that take place in the real work environment and are often combined with schooling that takes place in a classroom separate from the work environment (European Center for the Development of Vocational Training, 2021).

The European Center for the Development of Vocational Training (2021) defines apprenticeship learning as paid work experiences of at least 6 months that occur as a mandatory part of the curriculum in formal vocational training. Formal apprenticeship learning as part of vocational learning is very common, not only in Europe but worldwide, while the structure of apprenticeship

learning—how exactly it is combined with schooling, and how much time is spent in each of the settings—differs significantly between countries. However, a general finding across European countries is that combining an apprenticeship phase with schooling has a positive effect on employability ([European Center for the Development of Vocational Training, 2021](#)).

Apprenticeship learning in academic fields: the cognitive apprenticeship framework

To apply the beneficial aspects of the apprenticeship learning approach in highly academic settings, Collins developed the cognitive apprenticeship framework ([Collins 2015](#); [Collins & Kapur 2014](#)) developed the *cognitive apprenticeship framework*. As academic activities are hard to observe due to their largely cognitive nature, the cognitive apprenticeship approach describes aspects that need to be considered to make cognitive processes of experts accessible and to ensure that novices engage in meaningful cognitive activities and receive support when needed. The framework was originally targeted to be applied in K-12 schools and is based on research in such settings, but it has also been widely investigated in higher education settings ([Minshew et al., 2021](#)). Bringing together insights from a multitude of previous studies, the cognitive apprenticeship framework addresses four dimensions for successfully implementing the apprenticeship approach into academic settings: the content dimension (the types of knowledge that need to be focused on), the method dimension (how cognitive processes can be initiated and fostered), the sequencing dimension (in which order certain methods and cognitive processes should be implemented), and the social context (what social aspects need to be fostered).

Learning content: several types of knowledge

The goal of the cognitive apprenticeship approach is to promote the development of expertise and to enable learners to become active members of a community of academic practice. To achieve this goal, learners need several types of knowledge that go beyond the declarative and procedural knowledge of a given domain as is predominantly taught under the schooling approach ([Collins and Kapur, 2014](#)). Nevertheless, specific domain knowledge is also a central component in the cognitive apprenticeship approach. In the context of mathematics education, this may include understanding of specific terminology and mathematical signs, but also how to perform mathematical procedures. Besides domain knowledge, strategic knowledge is highly important as it allows learners to flexibly use their domain knowledge and to adapt to specific situations. Strategic knowledge, in the cognitive apprenticeship approach, refers to three types of knowledge ([Collins and Kapur, 2014](#)): heuristic strategies, which are effective ways to approach and solve typical problems; metacognitive strategies, which are ways to plan, execute, and reflect on learning and problem solving processes and assess the quality of the problem solving process and its outcome; and learning strategies, which enable learners to acquire new domain knowledge that seems necessary to solve a problem.

Methods in the learning process

According to the cognitive apprenticeship approach, it is necessary to (1) support learners in understanding and performing relevant practices on specific exemplary tasks, (2) help them generalize beyond the exemplary task, and (3) provide opportunities for them to proceed autonomously and in a self-regulated way beyond teacher provided tasks ([Collins, 2015](#)). The cognitive apprenticeship framework defines six specific methods that serve these goals ([Collins and Kapur, 2014](#)): cognitive modeling, coaching, and scaffolding serving the first purpose; articulation and reflection serving the second purpose; and exploration serving the third purpose.

Cognitive modeling aims at making invisible thinking processes of experts visible to the learners. To do so, teachers or experienced practitioners explicate what they think while solving a problem, such as a mathematical equation or interpretation of research data. This way, the order of thought processes and the way to approach a problem can be “observed.” Cognitive modeling can be implemented into learning processes in several forms. One prominent form is a live or video-recorded modeling example, in which a person demonstrates how to perform a problem solving process; another form is vicarious learning, in which another learner is observed while being taught to solve a problem by a knowledgeable person ([van Gog et al., 2019](#)). Worked examples are a third way of cognitive modeling: a classical worked example consists of an exemplary problem statement, a step-by-step description of the procedure to solve the exemplary problem, and the solution, whereas a heuristic worked example focuses on the underlying reasoning why certain choices are made during the problem solving process ([Mulder et al., 2014](#)). Combinations of these forms of cognitive modeling can also be used. Often not only correct ways to solve a problem are shown but also failed or erroneous attempts to approach the problem ([van Gog et al., 2019](#)).

Participating in relevant practices and doing on their own or in groups what experts do is a core aspect of (cognitive) apprenticeship. However, coming from the Vygotskian perspective that learning takes place in the zone of proximal development, until the learners become proficient in these activities and while they are still struggling, they need support when engaging in the practices. The cognitive apprenticeship framework describes coaching and scaffolding as the two core methods for supporting learners during their attempts to perform the practices. *Coaching* is a form of individual and personal support, for which the teacher needs to monitor students’ learning processes and intervene in the right moment, when a learner is stuck ([Collins and Kapur, 2014](#); [Collins, 2015](#)). However, monitoring cognitive processes in a typical classroom setting with a large group of learners as well as providing the right kind of support exactly when it is needed is a huge challenge. Researchers are, therefore, exploring ways to use technology to support teachers in these challenges. For example, teacher dashboards are a form of technological support which provides various information to teachers to help them see where individuals and groups of learners are in the learning process and whether help is needed ([van Leeuwen et al., 2019](#)). When help is needed, *scaffolding* comes into play. Scaffolding is a metaphor for all support measures that can be provided to students. An effective scaffold is contingent, that is, specifically tailored to the learner’s current need and, consequently, highly dependent on the teacher’s monitoring of the learning process;

it fades when learner abilities increase to avoid dependence on the scaffold; and while the scaffold fades, the responsibility for performing the task to be learned is slowly transferred to the student (van de Pol et al., 2010). Specifically helpful in this regard is feedback that makes learners aware when they are performing well and when problems show. Useful feedback may come from teachers or peers (e.g., Bolzer et al., 2015), but also from the learning environment. Intelligent tutoring systems are a digital learning environment that provides coaching and scaffolding in the form of a personal learning environment. Based on a model of the knowledge to be learned and a continuously updated model of the learner's current state in the learning process, intelligent tutoring systems adapt their support to the individual learner's needs and provide the right information and feedback exactly when it is needed, often using artificial intelligence (Mousavinasab et al., 2021). Intelligent tutoring systems have been successfully applied in many fields, including medical education, computer science, and language learning (Mousavinasab et al., 2021). Such systems are not meant to replace human teachers but allow them to provide optimal coaching and scaffolding in a clearly defined area of a domain when a large number of learners face a limited number of teachers, as it simulates a personal and adaptive master-apprentice-learning situation (Collins, 2015).

To foster deep understanding of underlying principles and avoid a situation where learning stays limited to specific situations and exemplary tasks or cases, the cognitive apprenticeship approach emphasizes *articulation* of and *reflection* about thought and reasoning processes. Prompting is an effective way to foster articulation and reflection, for example by triggering self-explanation of meta-cognitive processes (e.g., Bannert et al., 2015; Rau et al., 2015; Heitzmann et al., 2015). Having learners create representations to visualize complex content or arguments is another form of effective support (e.g., Ainsworth et al., 2011; Bell, 1997).

Finally, *exploration* fosters learners' autonomy in solving problems beyond what was done in the classroom and encourages them to find opportunities for learning and problem-solving on their own (Collins and Kapur, 2014; Collins, 2015).

Sequencing learning activities

In line with the curriculum of apprenticeship learning in communities of practice, the sequencing of learning activities is different from the schooling approach. However, as in a classroom setting, learning opportunities do not naturally emerge but need to be designed. Three rules can help to come as close as possible to the classical apprenticeship learning approach (Collins et al., 1988; Collins and Kapur, 2014; Collins, 2015). First, the bigger picture and main goal for learning needs to be clear to the learners before going into details of specific skills or tasks. Learners need a conceptual model of the overall task and what is important to complete the overall tasks, so they find it easier to understand why the details are important and can better monitor their learning processes accordingly. Second, to simulate peripheral participation, learners need to start with simple tasks and complexity increases in line with learners' increasing skills and knowledge. When the cognitive apprenticeship situation is well designed in this regard, learners often perceive feelings of success and rarely experience frustration. Third, to counteract the possible disadvantage of apprenticeship learning, that learners' do not generalize principles they learned but only apply them to the context in which the principles were learned, teachers need to foster cognitive flexibility (Spiro et al., 1991). To broaden but also deepen learners' knowledge and skills, the complexity of tasks and problems, as well as their diversity, needs to increase with learners' abilities.

Social context of learning

As the social context in which intermental activities take place plays a central role for apprenticeship learning, designing for meaningful social interactions and relationships is also crucial for the cognitive apprenticeship approach. The learning context in general requires a real-world or highly authentic learning task that comes with the inherent need for learners to acquire new knowledge and skills to solve a relevant problem. On the social level, this learning context needs to come with an inherent need for exchange and collaboration with other learners so a sense of community arises, as well as motivation and a sense of ownership for solving the problem (Collins, 2015; Collins and Kapur, 2014). This may be achieved by thoughtful implementation of collaborative learning or a learning community approach.

Conclusion

Apprenticeship learning has a long tradition and although it has, in many areas, been replaced by a schooling approach, it still exists in other fields, formally as well as informally. Looking at formal education, we see the benefits for bringing apprenticeship learning and schooling together and research provides evidence for the benefit of doing so. In vocational training, current trends show that combining phases of both approaches can be very beneficial to train persons that are well set for working in their job. On the school level, we see benefits of merging both approaches and this is also a strong field of ongoing research.

Critical thinking as a starting point

Critical thinking (CT) is a widely accepted educational goal and ideal. At the same time, it is a highly ill-defined construct, with scholars not yet in agreement regarding what exactly it refers to, and most importantly how it can be fostered and assessed.

Regarding its definition, a main division among scholars concerns whether CT refers to a constructive process of problem solving and decision making, or solely to an appraisal of intellectual products. Scholars defending the former (e.g., [Bailin, 1987](#); [Ennis, 2001](#); [Glassner and Schwarz, 2007](#); [Lipman, 1987](#); [Paul, 1987](#); [Perkins, 1985](#)) also tend to claim that critical thinking and creative thinking overlap, because generating any type of idea, solution, or decision is itself a creative process. Scholars defending the latter (e.g., [Ennis, 1993](#); [Scriven, 1976](#); [Sternberg, 1986](#); [Watson and Glaser, 1964](#)) tend to separate critical thinking from any demonstration of creativity. A second division within the CT scholarly community regards whether CT skills are subject-dependent or subject-independent. Although some scholars argue in favor of subject specificity in the development of CT skills (see for example [Glaser, 1984](#); [McPeck, 1981](#)), the majority of scholars argue in favor of a subject-general nature of CT (e.g., [Ennis, 1987](#); [Higgins and Baumfield, 1998](#); [Paul, 1990](#); [Perkins and Salomon, 1989](#)), justifying the transfer of CT skills to several contexts. However, and this leads to the third main division, CT is composed not only of skills but also of attitudes or dispositions as well as knowledge. If subject-matter knowledge is considered a component of CT, the question arises as to whether this subject-dependency extends to CT skills, or attitudes, or both ([Ennis, 1989](#)). The relation between these CT components remains an issue under exploration and an object of academic divide ([Hitchcock, 2020](#)).

Despite the ill-defined and variable nature of the term critical thinking, authors agree on (at least) its following characteristics:

Intentionality

Ennis (1996) defines CT as “reasonable reflective thinking focused on deciding what to believe or to do” (p. 166). Similarly, Halpern (1998) perceives CT as a way of thinking that can be applied to everything as long as it includes a “deliberate use of skills and strategies that increase the probability of a desirable outcome” (p. 449). This conscious and deliberate exercise of higher-order reflection is what makes thinking, applied to any context, critical. Intentional thinking is any thinking that is aimed at a specific purpose, and as such it implies a learner’s reflection on how (much) and whether the purpose has been achieved. According to Dewey (1966), in intentional thinking “natural active tendencies shall be fully enlisted in doing something, while seeing to it that the doing requires observation, the acquisition of information, and the use of a constructive imagination” (p. 137). In other words, intentional thinking is active thinking and learning (Freire, 1993, called it *authentic learning*.) Intentional thinking, and subsequent learning, is the core and outcome of reflexivity and criticality: the more intentional one becomes in one’s thinking, the more reflective and critical the thinking becomes, and vice versa (Bennett et al., 2016).

Sensitivity to context

As Lipman (1987) argued, critical thinking is self-corrective thinking, but for this to be possible, sensitivity to context and boundedness to principles are necessary conditions. The situatedness of CT in a concrete context is indisputable: We cannot ask someone to think critically in general, but we can ask her to, for example, critically analyze a text, or engage in a critical discussion of a topic (Moore, 2013). This is one aspect of context in relation to CT—i.e., the fact that it is contextualized in a situated practice. A second main aspect is the fact that it is discursive, and therefore it is both dialogical and dialectical, and therefore it needs to take several contexts into consideration. The fact that CT is discursive (i.e., expressed in intra- or inter-personal discourse) is rooted in its relation to reflection (see Dewey’s definition of CT above). CT needs some kind of information as an object of processing and reflecting on in order to formulate a judgment about something. This implies that critical thinkers engage in some type of situated, discursive reflection in order to validate the information being assessed or communicated to/from them. If they do not do that, their only other recourse, as Mezirow (1997) affirms, is to turn to an authority or tradition to do this validation for them. In this sense, CT is dialogical, as engaging in discourse means engaging in “a dialog devoted to assessing reasons presented in support of competing interpretations, by critically examining evidence, arguments, and alternative points of view” (Mezirow, 1997, p. 6). And it is also dialectical, as any argument made as part of a critical thinking process needs to confront existing or potential counterarguments (Paul, 1981).

Clarity and precision

According to Halpern (2014), “learning the skills of clear thinking can help everyone recognize propaganda and thus not fall prey to it, analyze unstated assumptions in arguments, realize when there is deliberate deception, consider the credibility of an information source, and think a problem or a decision through in the best way possible” (p. 11). However, such clarity and precision must always leave a space for flexibility in order to be critical. As Halpern (2014) again affirms, “a substantial increase in the likelihood of a desirable outcome is the best that critical thinking can promise” (p. 9). With this awareness acquired, a critical thinker sets goals and does the best to achieve these goals (there is much literature affirming that critical thinking is also persisting thinking; see for example Dewey, 1910; Faccione, 1990; Halpern, 2014). Yet if the desired outcomes do not materialize, the critical thinker is eager to modify the plan of action, as evidenced in problem solving involving critical thinking attitudes and skills (Paul and Elder, 2006). Being clear and precise while at the same time flexible is a quality of critical thinkers.

Boundedness to principles

Thinking well in any area requires knowledge, but it is its relation to principles of good reasoning that thinking becomes critical thinking (Siegel, 1980). Those principles, however universal or subject-related, are the ones that make thinking sound, credible, and accountable. Examples of these include principles of interpretation and criticism, as well as relations between principles of interpretation and standards of assessment, and between arguers and their audience (Govier, 2018). Groarke and Tindale (2004) also remind us that the key to success is not simply knowing the principles and criteria of good reasoning but, above all, employing them in practice. This can be done in two main ways: either individually, through critical thinking or problem-solving exercise, or publicly, through argumentation practices that require, and therefore imply, the application of such skills and standards of good reasoning. This idea that CT is individual reflective, rational and goal-oriented reasoning, while argumentation is the social practice of CT is further explained in **Argumentation as an alternative construct to critical thinking** section onwards.

Argumentation as an alternative construct to critical thinking

Argumentation can be defined as the use of language to support an uncertain or potentially uncertain claim, typically contending with a difference between two or more parties (Rapanta and Macagno, 2019). This difference includes the incompatibility of points

of view concerning an expressed position; however, it is not limited to it. An argument can be advanced to address different types of doubts: “an unsolved problem, an unproven hypothesis, or even a situation where both parties are blocked from further actions they are trying to carry out” (Walton, 1990, p. 411). According to Groarke and Tindale (2004), a good arguer, just like a critical thinker, “must be able to recognize and judge: what counts as a good reason for a claim; when claims are relevant to an argument, and when they are not; what conclusions reasonably follow from different kinds of evidence; the difference between sufficient and insufficient evidence; and the expectations that attend different contexts and different audiences” (p. XII). Critical thinking is about reasoning in a critical manner, and this is what argumentation is all about. What is then the difference between the two? The difference lies in the distinction between argumentation and reasoning.

Reasoning is defined by the process of making inferences, or inferring, with argument being one of the various purposes reasoning can have (Angeles, 1981). According to Woods et al. (2004), “arguments in the broad sense are interpersonal, social phenomena—a kind of public event. Inferences, in contrast, are essentially private affairs. They involve the adjusting of an individual’s mental states, or the transition from one belief state to another. Thus, they are something the individual handles solo” (p. 6). Said differently, reasoning is a tool for arguing, manifested in discourse *with* others (as in the case of academic writing) or *together with* others (as in the case of dialogical argumentation).

One of the main limitations of the construct of CT is the absence of consensus as to how to assess it and foster it. Although scholars tend to broadly agree that CT is reasonable, reflective, intentional thinking involving knowledge, skills, and dispositions, there is no consensus as to when and how CT is manifested. According to Siegel (1985), the important question is not, “Is there a generalized skill of critical thinking?”, but rather, “How does critical thinking manifest itself?” (p. 75). Kuhn (1999) similarly asks “What does it mean to be accomplished in thinking, and how does this accomplishment manifest itself?” (p. 16).

Argumentation as a discursive social practice is the “battlefield” in which CT’s main characteristics are not only manifested, but also developed. Many would claim this occurs through engagement in dialog with others (e.g., Burbules and Berk, 1999; Kuhn, 2019; Rapanta, 2019a; Walton, 1989). Here we focus on how argumentative reasoning—that is, reasoning to argue—invokes explicit, assessable standards for critical thinking to manifest in discourse and further develop. Such standards overlap with argument assessment criteria of an informal logic nature, such as: reasonableness, relevance, sufficiency, and acceptability.

Reasonableness

Reasonableness is the umbrella criterion that has the same function for informal logic arguments as the concept of validity has for formal logic—that is, providing a means for distinguishing between sound and unsound arguments (Zarefsky, 1981). Reasonableness, also called rationality, refers to the degree that the premises chosen as the most relevant to support one’s claims and arguments lead to “reasonable” or “rational” conclusions, or are reasonable or rational themselves. A reasonable or rational judgment is non-arbitrary, impartial, and objective (Siegel, 1980).

Among CT scholars, “reasonable” has been used to describe either a position (Ennis, 2011) or the criteria implied to support a position (Faccione, 1990). In terms of the former, it is not clear what a reasonable position refers to. Regarding the latter, Ennis (2011) adds that the reasonableness of criteria refers not only to their quality but also to their comprehensiveness: the critical thinker must “employ a reasonable critical thinking checklist” (p. 17). However, within the CT literature, reasonableness is not well-defined.

How can argumentation theory help us define the reasonableness/rationality of an argument? Several scholars (Chin and Osborne, 2010; Mayweg-Paus et al., 2016; Nussbaum and Edwards, 2011; Song and Ferretti, 2013) claim that this is possible through posing the right critical questions. Walton (Walton, 1996; Walton et al., 2008) made the connection between critical questions and argument context more explicit by identifying critical questions for various types of everyday arguments, according to whether they express deductive (e.g., causal, consequential), inductive (e.g., reasoning from example, analogical reasoning) or abductive (e.g., reasoning from sign, from best explanation) reasoning (Macagno, 2015). The so-called argumentation schemes are “stereotypical patterns of inference, combining semantic-ontological relations with types of reasoning and logical axioms and representing the abstract structure of the most common types of natural arguments” (Macagno, 2015, p. 192). Walton et al. (2008) provide a list of critical questions accompanying each scheme, according to the topical, material and dialectical relations expressed between the argument premises and its conclusion, as well as between the argument and other possible arguments (Walton, 1998). For the argument from expert opinion, for instance, the following questions apply (see also Rapanta and Walton, 2016):

- (1) Expertise Question (Q1): How credible is E as an expert source?
- (2) Field Question (Q2): Is E an expert in the field F that A is in?
- (3) Opinion Question (Q3): What did E assert that implies A?
- (4) Trustworthiness Question (Q4): Is E personally reliable as a source?
- (5) Consistency Question (Q5): Is A consistent with what other experts assert?
- (6) Backup Evidence Question (Q6): Is E’s assertion based on evidence?

Different critical questions apply to different types of arguments. Reasonableness relates to the CT aspect of intentionality, because the degree to which the arguer searches to anticipate and reply to the type of critical questions listed above is largely defined by how (much) she recognizes the (dia)logical purpose of the argument. In other words, the capacity of an arguer to anticipate potential counterarguments corresponding to the type of critical questions each argument may elicit is a sign of reasonableness and

a condition for the construction of sound arguments, as opposed to fallacious ones (for the relation between critical questions, argument premises and fallacies see [Walton, 2010](#)).

If reasonableness is the “umbrella” criterion for assessing informal arguments, or for creating valid ones, relevance, sufficiency and acceptability express how this informal soundness or cogency can be operationalized in the field of informal (everyday, ordinary) logic.

Relevance

Argument relevance does not merely imply that contributions are on the topic and coherent with the contents discussed. This is only one aspect of relevance, which, in argumentative dialog, corresponds to the so-called *structural* relevance—how the argument components logically inter-relate one with another ([Macagno, 2008, 2016](#)). The other aspect of relevance refers to being consistent with the *pragmatic* function—that is, the purpose of the dialog, and the different forms it may take throughout interaction ([Macagno, 2016, 2019](#)). In argument skill development terms, the former type of relevant participation is contained in argument strategic and metacognitive skills, whereas the latter is expressed through the idea of metastrategic and epistemological awareness (see [Reasoning abilities, skills and dispositions implied in argumentative discourse](#) section). Being sensitive to the criterion of relevance is equivalent to being “dialectically astute”; this means being “alert to the need for enough evidence of the right kinds, and to the possibilities of counter-arguments and conflicting evidence” ([Blair and Johnson, 1987](#), p. 51). Therefore, argument relevance largely fulfills the CT characteristic of sensitivity to context (see [Critical thinking as a starting point](#) section).

Sufficiency

If probative relevance is assessed by the criterion that “the premises of an argument ought to be relevant to the conclusion”, argument sufficiency refers to the requirement that “the premises ought to provide sufficient support for the conclusion” ([Blair and Johnson, 1987](#), p. 54). Similarly to relevance, sufficiency also has a dialectical component: to decide whether or not an arguer sufficiently defends a claim and its premises, we must imagine the dialogical context within which those claims and premises will be put forward. Critical questions accompanying argumentation schemes are useful in this task. For example, when deciding whether an argument from expert opinion is sufficiently supported or not, questions assessing the sources of this expertise can be asked (e.g., How many years of practice does Doctor X have in the field?). Or, when assessing the validity of an argument from generalization, the following sufficiency question can be asked: How big shall a sample be in order for a research study to be valid? Overall, it can be said that sufficiency is an aspect of relevance applying to the relation between premises and conclusion, referring to how explicitly (i.e., clearly and precisely) this relation is expressed. If an argument is sufficient in terms of support provided for the conclusion, it follows that it is also clear and precise. In other words, the more one reveals the different premises that support a claim, the more content and context is added to the presuppositions of an argument (see, for example, the statement “Jack is overweight” used by [Paul and Elder \(2013\)](#), to show how a claim can be clear but not sufficiently precise, because of the lack of explicit premises). Therefore, argumentative reasoning connects to the CT criterion of clarity and precision (see [Critical thinking as a starting point](#) section) through the informal logic criterion of argument sufficiency.

Acceptability

Acceptability of an argument refers to whether its premises should be accepted by an audience as they are, without further support, or not. Even in arguments that appear to be deductively valid (i.e., when the premises are true, then the conclusion is also true), it is often the case that the premises are debatable or open to discussion. In those cases, the burden of proof lies with the arguer, meaning that the arguer needs to provide further support for these premises to show they are themselves convincing. Similarly to relevance and sufficiency, acceptability is something that can only be assessed in the context of dialog, due to its strong relation to the dialogical concept of burden of proof ([Blair, 2012](#)). Moreover, because when an argument’s premises are relevant to the conclusion and support it sufficiently, they are also acceptable, we can also say that acceptability corresponds to the CT component of boundedness to principles (see [Critical thinking as a starting point](#) section).

In summary, in this section we showed that argumentation can be considered an alternative construct to CT, because it binds to the informal logic criteria of reasonableness, relevance, sufficiency and acceptability, which strongly relate to the main CT components described in [Critical thinking as a starting point](#) section. Moreover, we argued that these criteria are assessable or make sense in a dialogic context: given that argumentation is dialectical in nature ([Blair and Johnson, 1987](#)), an interlocutor is at least implicitly present or taken into consideration for argumentation to take place. The situatedness and functionality of these argument assessment criteria in the context of dialogic practice is highly important as they become criteria of both generation and appraisal, combining therefore the critical and creative aspects of argumentative reasoning (see also [Glassner and Schwarz, 2007](#), for a similar perspective).

In the next section we further explain how argumentative discourse reveals (i.e., brings to the surface) all the critical thinking abilities, skills, and dispositions otherwise difficult to access and assess.

Reasoning abilities, skills and dispositions implied in argumentative discourse

Ennis (1993) remarked on the difficulty of several critical thinking assessment tests to truly capture the CT skills and dispositions they attempt to assess, particularly, when the skills and dispositions are expected to be transferred and applied to different contexts. As an alternative, a “strong sense” approach to CT is necessary, one that does not rely on the assumption that CT is “a battery of atomic technical skills” (Paul, 1981, p. 3), accessible through an assessment test. Argumentation provides the opportunity for individuals to engage in a practice that includes the following: construct an argument to support a claim, identify and make use of relevant evidence, generate/anticipate counterarguments, and respond to counterarguments with rebuttals (Kuhn, 1991). In oral discourse, this series of activities translates into a persuasive dialog, where the goal of the participants is to adopt a position, to defend it as well as possible, and to seek to persuade the interlocutor of its merits over an alternative. In written discourse, this translates into persuasive or argumentative writing, where the goal of the writer is to consider various, often contrary, perspectives and to provide an integrated (two-sided) argument as result of the weighing of positive and negative evidence of each position. The inherent goal of persuasion in the practice of argumentation as manifested in externalized discourse (both oral and written) implies the presence of key reasoning abilities, skills and dispositions of a similar nature to those associated with CT.

Generative abilities

More and more in educational policy documents around the world, students are expected to “generate and evaluate scientific evidence and explanations” and “participate productively in scientific practices and discourses” (Duschl et al., 2008, p. 2). Science here is conceived broadly, as a type of reasoning based on inquiry and argumentation (Kuhn, 1992, 1993). The generation and appraisal of evidence and explanations as well as the productive participation in argumentative discourse are all generative/constructive abilities entailed in the practice of argumentation (as we saw in **Critical thinking as a starting point** section, this is not always so in the case of CT).

Generating arguments and participating productively in argumentative discourse imply the successful (reasonable, relevant, sufficient, and acceptable) construction of argument claims and premises, as well as theory-evidence coordination. Premises (reasons offered in support of a claim) can be of various types, also according to the type and content domain of the claim. For example, a claim about a social issue (e.g., abortion) can be of the type “in favor/against” whereas a claim about a scientific phenomenon needs to contain a hypothesis (e.g., “If I drop an object, it will fall”). Among the types of premises used to support a claim, Toulmin (1958) identified two, namely a warrant, or the inferential link between claim and data, and a backing, namely the evidence used to further support this inference. The warrant replies to the “Why do you say so?” aspect of argumentative reasoning, while the backing to the “How do you know this is so?” (Kuhn, 1999, 2001). The theory-evidence coordination is a necessary aspect of generating an argument not only because of the selection of the right premises that will function as a support of it but also because of the necessary consideration of limitations (restrictions) to one’s own reasoning, structurally conceived by Toulmin (1958) with the argument element called “rebuttal.” Fig. 1 shows an example of the main argument structure of both a social and a scientific argument, with their premises (warrant and backing) and a potential rebuttal for each.

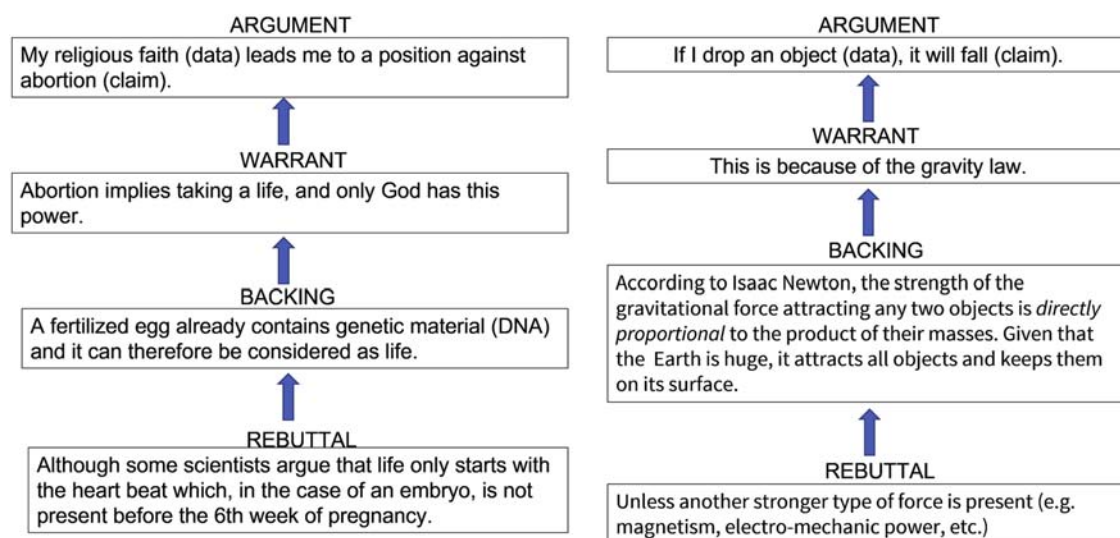

Fig. 1 An example of a social (left) and a scientific argument (right).

Inferential abilities

According to [Henderson and Horgan \(2009\)](#), “inferential processes, broadly understood, are simply those cognitive processes in which beliefs are formed or maintained on the basis of the information possessed” (p. 301). These inferential processes are usually considered equivalent to reasoning, as reasoning describes “the making or granting of assumptions called premises (starting points) and the process of moving toward conclusions” ([Walton, 1990](#), p. 403). When it comes to the relation between inference/reasoning and argumentation, [Walton \(1990\)](#) claims that reasoning occurs *within* discourse or argument, whereas other scholars attest that reasoning is discourse or argument (see [Walton, 1990](#), for the distinction). In either case, inferential reasoning is a requirement for argumentative discourse, and at the same time appears during it. A view of argumentation as a dynamic and dialectical type of reasoning occurring in certain contexts of dialog is thus justified under this approach.

Appraisal abilities

Appraisal, or evaluation, abilities can be regarded as part of generative abilities, but can also be considered independently, when assessing arguments produced by others. From an argumentation perspective, the following appraisal activities are part of the reasoning processes necessary for the practice of argumentation to take place:

Evaluation of information

A complementary process to argumentation is that of inquiry. Inquiry abilities are about “recognizing that there is something to find out—that new evidence can be distinguished from and potentially bears on existing understanding—and identifying what this something is within the context of any specific inquiry activity” ([Kuhn and Pease, 2008](#), p. 513). Evaluating available information and its potential use as evidence to support or rebut one’s arguments is part of the ability to evaluate information in relation to the context of the activity in which such information is used. [Dewey \(1910\)](#) was the first to claim that thinking is uncritical when it lacks reflective inquiry. For him, reflective, critical, and good thinking are synonyms, although he preferred using the term reflective thinking to refer to “active, persistent and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it, and the further conclusions to which it tends” (p. 6). This implies that a certain degree of judgment suspension is necessary, including the “search for new materials to corroborate or to refute the first suggestions that occur” (p. 13). However, such judgment cannot be ongoing; otherwise it cannot direct inquiry and examination (p. 108). Argumentation provides a context for inquiry to be directed toward the goal of constructing adequate, coherent, and consistent explanations based on information at hand ([Sampson et al., 2011](#)).

Evaluation of arguments

All the “good reasoning” criteria described in **Argumentation as an alternative construct to critical thinking** section are dialectical in nature, meaning that they all have a dialogical component that defines their satisfaction or not, even when arguments are constructed individually (i.e., not socially). Furthermore, in order for individual arguments to be reasonable (i.e., fallacy-free), the arguer must consider any objections a reasonable critic of these arguments might raise ([Blair and Johnson, 1987](#)). This is possible through the argumentation skill of antilogos, which is the ability to critically evaluate whether specific information can support different claims ([Billig, 1987](#); [Glassner and Schwarz, 2007](#)), and subsequently coordinate theory (claims) with evidence (information) ([Kuhn, 1999](#)). This skill is manifested in the production of counterarguments to one’s own arguments, and of responding to those through oral rebuttals or through written integrated (two-sided) arguments.

Evaluation of context

Evaluating when and whether to engage in critical thinking is another ability involving argumentation, evidenced by several argument-based instructional programs around issues that are worthy of investing mental energy in order to choose the best among several explanations. As [Halpern \(1998](#), p. 452) puts it, “an extended session of generating alternatives and calculating probabilities is a reasonable response to a diagnosis of cancer; it is not worth the effort when the decision involves the selection of an ice-cream flavor”. But what makes an issue one worthy of argumentative inquiry and contemplation? The following are some of the characteristics of an issue meriting argument: (a) the issue is related to a problem or phenomenon under consideration; (b) it is questionable or open to discussion; and (c) it is addressable through use of information as supporting evidence ([Rapanta, 2019b](#)). Recently, [Kuhn \(2018a\)](#) provided a list of authentic real-world issues that serve well as a context for argumentation. These issues relate to topics of gradually expanding scope, from personal to community to national and global; their common dimension is that they are addressable in terms of two or more contrasting alternatives with evidence pertinent to both sides.

Metastrategic skills

A series of empirical studies show that argument skills are multifaceted, involving both strategic skills, such as the ability to construct counterarguments and use evidence, but also metastrategic ones. Studies examining the development of argument skills, using the microgenetic method, revealed that a metastrategic understanding of the norms of argumentation was developing and supported development of argument skill ([Kuhn et al., 2008, 2013](#); [Iordanou and Constantinou, 2015](#); [Shi, 2020](#)). Participants who engaged in extensive practice in dialogic argumentation, in addition to the gains at the strategic level—use of counterargument strategies

aiming to weaken other's position—showed significant gains in meta-level communication *about* the discourse (Kuhn et al., 2008). The meta-level communication became more reciprocal over time and took a directive character, showing an attempt to direct the argumentation process (Kuhn et al., 2013). Those findings suggest that meta-level awareness and understanding of argumentation is developing through engagement in dialogic argumentation and supports the development of argumentation strategies, at the performance level. The co-existence of gains at the strategic and metastrategic level is consistent with other findings in cognitive development literature suggesting a bootstrapping relation between strategic and metastrategic levels (Kuhn and Pearsall, 1998), that is, between applying argumentation strategies at the performance level and the meta-level awareness of the process of argumentation.

Epistemic and epistemological awareness

The meta-level component of argumentation involves besides metastrategic knowledge, epistemic awareness. Epistemic awareness involves appreciation that counterargument and evidence use are critical components of argumentation (Kuhn et al., 2013). The growing attention to others' position, evident in individuals' inquiry skills—looking for information about other's position—and the use of counterarguments weakening others' position, while engaging in dialogic argumentation (Iordanou and Kuhn, 2020) is evidence of an implicit developing epistemic awareness that other's position might have some merit and is worthy of our attention. The increasing use of counterarguments and evidence may also reveal an epistemic appreciation of the function of counterargument and evidence as a means for persuading others, but also reveal another prominent epistemic achievement, namely, an appreciation of the subjective nature of human knowledge and the acknowledgment that there might be alternative interpretations of a particular phenomenon which are worthy of our attention.

Epistemic awareness also involves one's epistemic standards, that is, the standards used to evaluate knowledge claims (Chinn et al., 2020). Epistemic standards change developmentally, moving from egocentric to more objective ones. For example, three-year-olds show preference for egocentric standards, such as familiarity with the informant, while older children employ more objective standards, showing preference toward informers who have been reliable in their past performance (Corriveau and Harris, 2009). Underlying developmental changes in epistemic awareness are also changes in epistemic understanding regarding evidence and its coordination with theory, such as understanding that evidence is different from a claim and that different information leads to different beliefs (see Iordanou, 2016a).

Epistemic standards involve issues such as judging the credibility of the source of a piece of information and trustworthiness—Who can I trust to get evidence? Involving further questions such as “Who is an expert?” but also “Which media source can I trust?” and are closely related with one's science media literacy (Allchin, 2021).

Reasoning/arguing disposition

Engagement in argumentation, involving both construction and critical evaluation of arguments, depends not only on whether individuals have the knowledge and skills to do so—including both strategic and metastrategic knowledge—but also on whether individuals have the disposition to engage in this task. The disposition to engage in argumentation is affected by individuals' values and epistemic thinking (Kuhn, 2001). Epistemic thinking, besides involving one's epistemic commitments regarding which sources are trustworthy and what kinds of evidence are reliable, involve one's appreciation of which standards and methodologies are most appropriate for deciding what is true (Chinn et al., 2020). Valuing argumentation as a reliable and appropriate methodology for achieving truth and as the most powerful means of influencing others is a prerequisite for engaging in fruitful argumentation.

According to the developmental model of epistemic cognition (Kuhn et al., 2000), epistemic understanding develops, progressing from the absolutist level—where knowledge is conceived as an objective, external entity, which is knowable with certainty—to the multiplist level—where knowledge is conceived as a subjective construct of the human mind—to the evaluativist level—where a balance is achieved between the objective and subjective components of knowledge and knowledge is viewed as the product of evaluation based on argument and evidence (Kuhn et al., 2000). Empirical findings showed that there is a relation between mature epistemic understanding—the evaluativist level—and engagement in both argument evaluation (Iordanou et al., 2019) and argument construction (Iordanou et al., 2020; Mason and Scirica, 2006).

In addition to epistemic beliefs, egocentric biases and affect influence reasoning disposition and the quality of reasoning. Individuals tend to show my-side bias in reasoning when dealing with an issue that they hold strong beliefs about, that is, a favoritism toward egocentric arguments, which are in line with one's own views or beliefs (Baron, 1995). Depending on the source and/or whether they read something that is in agreement with their beliefs or not, individuals with strong beliefs on an issue show avoidance or engage in different kind of reasoning (Iordanou et al., 2020). Finally, high emotional investment affects one's reasoning disposition and leads individuals to biases in reasoning, such as rating opposing arguments as weaker, known as the disconfirmation bias (Edwards and Smith, 1996).

Finally, argumentativeness can be defined as the disposition “to attack the other arguer's case, reasons, position, and evidence” (Rapanta and Hample, 2015, p. 266). Argumentativeness is a motive for someone engaging or not in an argumentative dialog, with either negative (anti-social) or constructive consequences (Infante, 1988). The idea behind argumentativeness as a positive disposition is that “when individuals engage in argumentativeness, they attack the positions that others take or hold ... When individuals engage in verbal aggression, they attack the self-concept of the other” (Rancer, 1998, p. 152). Seen as a contrary disposition to being verbally aggressive, being argumentative can be related to critical thinking as it requires a degree of self-evaluation and self-reflection.

Evidence from argument-based pedagogical methods designed to foster students' critical thinking skills and dispositions

According to Kuhn (2019), rather than an individual ability or skill, "critical thinking is a dialogic practice people engage in and commit to, initially interactively and then in interiorized form with the other only implicit" (p. 146). This idea is rooted in socio-cultural theories of learning (Mead, 1934; Vygotsky, 1987a), according to which thinking is a social practice that is facilitated and developed through interaction with others. It is only after engaging with others intermentally, that practice and its gains are also transferred to the intramental level (Wertsch, 1985). This view of thinking in general, and of critical thinking in particular (see Larrain et al., 2019), underlies the vast quantity of empirical research on dialogical, argument-based pedagogical methods reporting gains subsequently transferred to individual tasks. This section is dedicated to review of some of these works by identifying some major ways in which skills and dispositions exercised or "put in service" in dialogical argumentation may transfer to individual practices manifesting critical thinking.

Transfer from social to individual: the case of writing

From a sociocultural learning theory perspective, it is expected that part of the knowledge negotiation process taking place socially, through dialog, is then transferred to individual writing products (Vygotsky, 1978). For example, Chen et al. (2016) showed that students' writing in science improved over time following engagement in peer-to-peer negotiations and whole-class presentations followed by peers' critique. They maintain that the most important reason for this improvement is the "advanced awareness of audience" (p. 313), which then become part of students' reasoning in their development of written arguments. Similarly, Sampson et al. (2013) showed how a writing-intensive instructional approach may enable adolescents to advance their writing skills through engaging in group writing processes as part of science laboratory courses. In a non-science context, results are similar. For example, Reznitskaya et al. (2001) showed how primary school students' engagement in small-group discussions on controversial issues about texts they had read significantly improved their subsequent persuasive essays.

Kuhn and colleagues in a series of studies (e.g., Hemberger et al., 2017; Kuhn et al., 2016a,b; Kuhn and Moore, 2015; see also Iordanou and Rapanta, 2021, for a review) have shown that dialogical argumentation is a path to argumentative writing and its development. They showed that young adolescents engaged in an extended dialog-based program of peer argumentation, "Argue with Me," not only improve their discourse but also their argumentative writing. For example, Kuhn and Crowell (2011) found the intervention group wrote more dual-perspective arguments than a comparison group at the end of Year 2, and more integrated-perspective and more arguments in general in Year 3.

Transfer to other topics/context

Due to the prevailing methods of assessing CT as a set of individual responses to a set of closed-ended content-specific questions, the issue of whether CT skills and dispositions are transferable to different domains remains unresolved (Ennis, 1989; Halpern, 1998). Arguments in favor of CT domain-dependence consist of the following: that thinking always needs something to be applied to (Paul, 1985); that different fields have different types and challenges of reasoning (Toulmin et al., 1979); and that skills applied to resolve one task or problem may not be necessary for a different task or problem (McPeck, 1981). Arguments in favor of CT domain-independence mainly consist of the following: that high order cognitive skills are not content- but context-bound (Perkins and Salomon, 1989), where context can bring them to the surface (Resnick, 1987); that the question is whether knowledge of the field is a necessary or sufficient requirement for CT to emerge (Ennis, 1989); and that dispositions, which are content-free, may influence the ways knowledge and skills are applied (Ennis, 1996).

Empirical studies of argumentation have addressed the issue of transferability of CT skills to other contexts. Iordanou (2013) showed that the gains in the electronic dialog mode, in particular increased levels of counterarguments and rebuttals, successfully transferred to the face-to-face dialog mode. Iordanou (2010) also showed that transfer of argumentative reasoning gains occurred in both directions from arguing in the science to social domain and vice versa. Several other studies (e.g., Hemberger et al., 2017; Iordanou and Constantinou, 2014; Kuhn et al., 2016a; Iordanou and Kuhn, 2020; Papathomas and Kuhn, 2017; Reznitskaya et al., 2012; Shi, 2019) confirm that transfer of reasoning gains to a new topic beyond the one students engage with in discourse is possible. Finally, recent studies also showed that transfer from "learning to argue" to "arguing to learn" contexts (Muller-Mirza and Perret-Clermont, 2009; Von Aufschnaiter et al., 2008) is possible. In particular, students who engaged in intensive dialogical argumentation practice on a topic either showed reasoning gains on another, curriculum-related topic (Rapanta, 2021), or even content knowledge learning gains (Iordanou et al., 2019b). In summary, because meaningful learning requires deep engagement with ideas, and the practice of argumentation provides the context for this (Jonassen and Kim, 2010), gains related to both the "deep engagement" process as well as "ideas/knowledge" learning are possible, confirming the two-fold metaphor of learning as participation and as acquisition (Sfard, 1998).

From skills to dispositions

Another type of transfer is that from manifested skills to dispositions. Immersion in the practice of dialogical argumentation may affect not only how much and how well students argue but also their stance regarding the value, purpose and norms of argument.

This can be considered a type of transfer from CT skills to CT dispositions. Studies, for example, reporting on improvements in argument evaluation tasks after students engage in dialogical argumentation, or after their recognition of argumentation norms, confirm this relationship (e.g., [Ryu and Sandoval, 2012](#); [Weinstock et al., 2004](#)). Learning the epistemological norms of dialogical argumentation through applying them in practice and transferring such learning to a dialog construction and evaluation task is another type of evidence of transfer from skills to disposition (e.g., [Kuhn et al., 2013](#)). Transfer is also confirmed when the tasks manifesting improvement or change in epistemological dispositions are related to concepts of knowledge and reasoning in general. Again, engagement in dialogical argumentation practice was shown to produce such transfer. For example, [Iordanou \(2016b\)](#) showed, in a pre/post-intervention assessment, that students' engagement in intensive dialogic practice had a positive effect on their understanding or reasoning and knowledge in general.

Transfer from skills to dispositions can also be implicit (i.e., without manifestation in a transfer task) as several argumentation skills "contain" certain dispositions. For example, [Kuhn \(1991, 1999\)](#) showed that advanced use of argument skills (generation of valid arguments, counterarguments, and rebuttals) implies the presence of advanced epistemologies pertaining to an evaluativist in contrast to an absolutist or a multiplist (see also [Reasoning/arguing disposition](#) section). What is more, the acquisition of such advanced epistemologies is itself developed through people's immersion in dialogical argumentation ([Iordanou and Kuhn, 2020](#)). According to [Anderson et al. \(2001\)](#), "the ability and disposition to take more than one perspective arises from participating in discussions with others who hold different perspectives" (p. 2). This multiperspectivism requires that at least two different or opposite perspectives are acceptable at the same time, and what makes one better than the other is the fact that it better fulfills the criteria of relevance and sufficiency discussed in [Argumentation as an alternative construct to critical thinking](#) section. Fulfillment of such criteria increases the plausibility of a perspective against an alternative ([Walton, 1989](#)). Considering that the degree of plausibility may change according to new information and its use as relevant support for one position or another is the basis of the evaluativist epistemology, developed through participation in persuasive argumentation, also referred to as inquiry dialog ([Reznitskaya and Gregory, 2013](#)).

Critical thinking as an endpoint

Argumentation, as discussed above, is a socio-discursive practice that functions at several levels (i.e., cognitive, metacognitive, epistemological) and those functions imply the application of CT abilities, skills, and dispositions. Therefore, argumentation provides a "visible practice" tool for identifying and assessing students' CT. At the same time, much empirical research shows that systematic engagement in dialogical argumentation helps develop reasoning skills and dispositions of a CT nature. Therefore, argumentation is also a vehicle for fostering and developing CT. However, for argumentation to be of a high quality, a degree of criticality is necessary. Such criticality is reflected in the values, reflexivity, and media and information literacy implicit in good argumentation.

Values

Values, both personal and social, can be used to support one's claims during argumentation. Values are considered to provide legitimate support to claims when they express "generalized conceptions of what are desirable ends or ways of behaving" ([Rieke et al., 1997](#), p. 10). Not all personal values are legitimate, as they can go against the common-sense "good"; therefore, we can talk about negative social values, such as social hatred. When such values are used as support for one's claims, a functional argument analysis does not always reveal the value-based unreasonableness of the arguments made. An analytical system combining functional analysis with content analysis (e.g., based on social representations) is necessary to this end (see [Rapanta and Trovão, 2020](#), for an example).

From an educational practice point of view, for argumentation to be critical, authenticity of the issues discussed as well as possible engagement in action as a result of the decisions taken are necessary criteria. Authentic issues are situated in real or realistic contexts ([Evagorou et al., 2011](#)), so that participants relate to them, and show willingness to engage at all levels of interaction (i.e., cognitive, metacognitive, epistemological). The enactment of the decisions taken as part of an interpersonal argumentation activity can help foster an ethical and activist stance ([Moore, 2013](#)) related to informed actions emerging from the discussions.

Reflexivity

On one hand, engagement in dialogical argumentation is necessary, as we showed above, for the social aspects of CT to be manifest and taken forward. On the other hand, individuals' engagement in argumentation is not enough for critical decision making and problem solving to take place. Finding a balance between the individual thinking process implied in CT and its social influence is key ([Rieke et al., 1997](#), p. 18). This balance can be achieved through the process and practice of reflexivity, which "occurs whenever a person interacting within a context elaborates the effects of their actions in an inter-subjective dynamic (...) gives new meaning to the processes (...) and recognizes the active role they assumed in guiding events" ([Freda and Esposito, 2017](#), p. 5). During argumentation, this can be achieved through the combination of the social reasoning activities with self-reflexive or peer-to-peer reflective activities as the one introduced as part of the "Argue with Me" method ([Kuhn et al., 2016b](#)): As pairs of peers argue against each

Let's think... Starting with our argument

One of our MAIN ARGUMENTS was:

Their COUNTERARGUMENT against our argument was:

Our COMEBACK was:

Fig. 2 Extract from the reflection tools used as part of the “Argue with Me” method. Courtesy of Prof. Deanna Kuhn.

other on a debatable topic of their interest, they also reflect on how their arguments are getting stronger or weaker during interaction by completing the diagram in Fig. 2. In general, graphical and diagrammatic representations have been shown to be effective in enhancing the self-reflexivity required for critical thinking and argumentation (Harrell and Wetzel, 2015).

Media and information literacy

Another challenge that adds to being critical in arguing relates to a competence complementary to argumentation, namely inquiry. According to Kuhn (2019), “inquiry and argument can be regarded as twin pillars of skilled thinking, replacing the more generic critical thinking label, if we regard inquiry as an input process of seeking and analyzing new information and argument as an output process of drawing and communicating justified conclusions” (p. 147). Inquiry skills are related to media and information literacy skills (Chu et al., 2011). Research needs to be done on how media, information, and argument literacy skills can be fostered together as a whole, with different but related tasks aiming at inquiry and argument.

Conclusion

The ideas presented in this article further substantiate the argument already formulated by Piaget (1928), and later articulated by Vygotsky (1987b), that reflective/critical thinking develops only in argument and discussion. It is through justification, counterargument and response (Leitão, 2000) that argumentation supports not only the construction of content knowledge (i.e., conceptual learning) but also and mainly the acquisition and development of argument knowledge, what is known as “learning to argue” (Muller-Mirza and Perret-Clermont, 2009). Argument knowledge entails a range of abilities, skills, and dispositions inherent to argumentative reasoning and discourse that almost fully cover the range of abilities, skills, and dispositions expected from a critical thinker. This justifies the extant use of argument-based instructional programs around the world explicitly aiming at the development of critical thinking skills through engagement in argumentation, and in particular, dialogic argumentation. The skill of *antilogos* (Billig, 1987), a necessary aspect of arguing, is also the basis of thinking critically. As argumentation theorist Walton (1989) puts it: “the common core of basic critical thinking skills underlying critical reasoning (...) is the key ability to look at both sides of an argument. The structure behind this ability is the concept of argument as dialogue” (p. 182).

The inherent relation of argumentation and critical thinking must become more explicit in educational research, so that the use of argumentative practices as a vehicle for critical thinking development can be further validated. One way to do so is through making explicit use of theoretical concepts and ideas from informal logic and argumentation theory and adapting them to pedagogical purposes. An example is Erduran et al. (2004) adaptation of Toulmin’s (1958) structural model of argument as a rubric for assessing classroom-based dialogical arguments. Another example is Kuhn’s (Kuhn et al., 2016a,b) inspiration from Walton (1989, 2014) to construct an argument-based curriculum focusing on increasing the plausibility of one’s own arguments while at the same time decreasing that of his/her components, first orally, as part of a social practice, and then individually, as part of a written essay. Another way is through making the connection between inquiry and argumentation more explicit in the various

instructional programs aiming at critical thinking development. Although argument-based inquiry and inquiry-based argumentation are already in use as instructional paradigms (see [Rapanta and Felton, 2019](#), for a review), especially in science, their broader use in contexts combining media, information, and argument literacy skills is still scant.

To conclude, argumentation and critical thinking (CT) are two sides of the same educational ideal: preparing reasonable and reflective democratic citizens, able to take decisions trusting their own analytical, appraisal, and argument construction skills. What is more, against the failure of CT assessment tests to provide the necessary link between what they define as good CT performance and what the necessary skills are to do so ([Kuhn, 2018b](#)), argumentation provides a way of both appraising and fostering CT abilities, skills, and dispositions as described in **Reasoning abilities, skills and dispositions implied in argumentative discourse** section. Together with inquiry skills, necessary for information search and selection, argumentation gets us closer to “empirically identifiable skills or behaviors than does the term critical thinking, while capturing much of what critical thinking is envisioned to encompass” ([Kuhn, 2019](#), p. 147). Although much work remains to be done in regard to assessing and fostering argument, adaptable to different contexts and domains (see [Iordanou and Rapanta, 2021](#)), argumentation as an instantiation of CT and as a pedagogical method and objective is a promising pathway to preparing 21st century students and citizens.

Introduction

Research on *computer supported collaborative learning (CSCL)* covers how to design the technological contexts for productive collaboration and how people learn in the context of collaborative activity. This is to optimize high level collaborative activities for sharing and building knowledge. The sharing and construction of knowledge among the participants in groups supported by technology is at the center of communication and can become a shared resource of group members (Stahl and Hakkarainen, 2021). CSCL can be designed to facilitate high-level cognitive achievements in educational settings in both online and classroom learning environments. It can occur synchronously or asynchronously, and can be realized in dyads, small study groups or work teams, but also in broader social networks and communities. Currently, CSCL has been implemented as part of various teaching and learning models at different educational levels and in work-life teams. It has increasingly been acknowledged for empowering learners as agentic participants in communities of learners to become authors of their future (Rosé and Järvelä, 2020). *Collaborative learning (CL)* is a powerful way of enhancing individual learning and can also be effective in developing group working skills and practices. It has origins both in sociocognitive theory, in terms of the social construction of knowledge, and in sociocultural theory, extending the view from learners' thinking and interactions to community- and cultural-level knowledge practices. Knowledge construction in CSCL is built by students' interactions, by means of the negotiation of meaning and the co-creation of knowledge (Resnick, 1991). The social construction of knowledge is commonly made via technology-mediated collaborative efforts through dialogs and facilitated by differences in persons' perspectives. By definition, collaborative learning is a coordinated effort to solve a problem or perform a task together by constructing and maintaining a shared conception of that problem (Roschelle and Teasley, 1995).

Productive CSCL

Productive CSCL can be explained from *sociocognitive* and *sociocultural*, as well as *linguistic perspectives*. Foundational sociocognitive research on small group interaction (e.g., Mugny and Doise, 1978) has focused on individual cognition and learning and has shown, for example, that confrontations in terms of socio-cognitive conflict are beneficial for learning when the conflict confrontation leads to conflict regulation in an epistemic manner. Sociocultural theory, having roots in Vygotsky (1978) thinking, emphasizes learning taking place first intersubjectively and then intrasubjectively and as a process of constructing a shared meaning (Stahl, 2004). Learning is viewed as a process of enculturation and participation in a community of practice. In addition to group interactions and social practices, tool-mediated activities (e.g., through or around computers) also play a crucial role in cognitive development and learning. From the linguistic perspective, building and maintaining a common ground means that individuals negotiate about common goals and construct shared understanding, knowledge, beliefs, assumptions, and presuppositions (Clark and Schaefer, 1989). These are prerequisites for the coordination of collaborative activities and knowledge sharing. However, while not merely sharing a common ground triggers learning, the core is the cognitive effort put into building shared understanding (Schwartz, 1995).

Productive collaboration can be enabled and enriched by computers and digital technologies. Group participants learn when they engage in collaborative activities, which trigger particular kinds of learning mechanisms. Collaborative learning situations supported by computers can provide a natural setting for externalizing thinking by explaining, questioning, arguing and sharing regulation. Collaborative technologies offer tools for exploring and experimenting with alternative solutions to problems as well as for representing and modeling knowledge (Fischer and Mandl, 2005). Therefore, CSCL provides environments that mediate collaborative interaction and learning in diverse ways. The tools through which interactions between learners, groups and artifacts take place mediate both interactions and materially embodied interactions (Davidsen and Ryberg, 2017). This is to say, interactions in CSCL environments happen between minds, but are also mediated by a variety of resources such as technology, language, gestures, prior knowledge or previous interactions (Stahl et al., 2006).

Shared meaning making in social interactions

The process of grounding refers to coordination of both content and process in communication and has been used to explain short conversational events in CSCL (Clark and Schaefer, 1989). Later research has focused more on shared meaning making (Stahl, 2004). Meaning making refers to “the increased cognitive-interactional effort involved in the transition from learning to understand each other to learning to understand the meanings of the semiotic tools that constitute the mediators of interpersonal interaction” (Baker et al., 1999, p. 31). Collaborative learning takes place through processes of shared meaning making, and there is a dynamic relationship between shared meanings and individual interpretations. During this process, learners negotiate their individual views to reach a shared understanding, which is used as a resource for constructing further understanding (Stahl et al., 2006).

The positive effects of social interaction for individual learning have been demonstrated in many of the earlier studies focusing on causal links between the conditions and effects of collaboration. Later research has started to focus on particular processes, mechanisms and contexts that either support or constrain the co-construction of knowledge (Dillenbourg, 1999). The theoretical ideas behind knowledge co-construction follow Roschelle's (1992) notion of convergence; group members *construct shared meanings* by constantly monitoring the degree to which they understand each other's thinking, extend other people's ideas, acknowledge divergent interpretations and resolve inconsistencies between the ideas that have been proposed. In sum, prior research has shown that when learners externalize and explain their still-developing understanding to each other, they learn more effectively (Baker et al., 1999). This can be supported by shared workspaces with a variety of representation tools provided by computers that enable learners to externalize their ideas and to co-construct shared representations (Fischer and Mandl, 2005).

Decades of research has shown *communication and interaction patterns* that impact the quality of processes in sharing meaning (e.g., Baker, 2009). Key interaction patterns, such as task-focused participation, which impact the quality of information synthesis making among group members have been identified. Equity in participating interactions is the extent to which all members contribute to the discussion process. Inability to integrate important ideas from group members may lead to reduced potential for collaborative problem solving (Borge and White, 2016). By developing joint understanding, a group ensures ideas are understood among team members by requesting clarifications, rewording and rephrasing. Successful groups develop a joint understanding of ideas in order to establish common ground or mutual knowledge (Clark and Schaefer, 1989). Failure to develop a joint understanding hinders group task engagement. Building joint ideas is the extent to which a group elaborates interactions to ensure that contributions and ideas are not ignored or accepted without discussion. If this does not occur, loss of information may lead to poor decision-making outcomes (Barron, 2003).

Group level information processing covers several critical patterns in interactions that contribute to successful collaborative knowledge construction. Exploring alternative perspectives and explanations allows group members to present alternative ideas, opinions and claims. If the group agrees with the first possible opinion rather than exploring alternative solutions, this may lead to a lack of innovative thinking and to routine solutions. Studies show that the power of collaborative learning may fail if group members simply acknowledge or ignore other group members' contributions, rather than explore and extend them (e.g., Jeong and Chi, 2007). Then, a group simply transfers a set of existing individual ideas to other members rather than creating new knowledge that no group member had before (Webb et al., 1995).

Deep argumentation consists of high-quality claims, whereas lack of critical evaluation and analysis of information may lead to weak argumentation quality (Weinberger and Fischer, 2006). In general, collaborative argumentation allows students to consider and recognize divergent views, find discrepancies in understanding and negotiate meanings (Baker, 2009). For example, in CSCL, learners can argue collaboratively and co-constructively, deliberating and reasoning together in order to improve their understandings of the topic at hand, rather than each trying to “win” (Asterhan and Babichenko, 2015). Collaborative argumentation can also be regarded as a type of interaction process that may support group coordination. Computers can support the process of argumentation by making the interaction process more visible and tangible for the learners (Andriessen et al., 2003). Engaging in argumentative and constructive discussion consists of respecting social norms for other members' ideas and for equal participation (Blumenfeld et al., 1996), whereas disruptive discussion and unfavorable socioemotional interactions can lead to psychological unsafety that impacts group members' ability to learn from each other. These interaction patterns can impact how groups develop knowledge and the quality of the knowledge that is developed in CSCL. They affect the extent to which a group uses its members as cognitive, motivational and emotional resources; uses resources provided by technology; establishes productive common ground; and develops new knowledge or solutions that did not exist before collaboration.

Productive collaborative learning and working is a *multifaceted interaction process* that integrates cognitive, motivational and emotional components as the core of collaboration (Borge et al., 2018; Ludvigsen, 2016). In theory, collaborative learning requires group members to be aware of and to coordinate their cognitive, metacognitive, motivational and emotional resources and processes (Hadwin et al., 2018). In practice, starting points for successful CSCL are working in line with shared goals, sharing of knowledge and understanding, and joint monitoring of collaboration processes. Therefore, sharing has also been conceptualized as *metacognitive-level interactions*, and the *concept of regulation* in terms of self-regulation, co-regulation and socially shared regulation has been introduced to CSCL (Järvelä and Hadwin, 2013). Increasing evidence shows that it is not only an individual's but also a group's shared processes that matter, and for this reason, regulating collaborative learning is critical for success (Zheng et al., 2019).

Designing and supporting CSCL

Important questions that are being investigated in research on CSCL are: why do some groups perform better than others, how do learners engage in deep level collaborative interactions, why do they want to extend each other's understanding, and why do they sometimes fail in attempts to work as an effective group? As described earlier, research has explained these problems from different angles during the past decade, and efforts have been made to design and support productive CSCL. Effective collaborative learning does not occur automatically, but it can be designed. Technology affords learner opportunities to engage in a joint task, communicate, share resources, engage in productive collaborative learning processes, engage in co-construction, monitor and regulate collaborative learning, and find and build groups and communities (Jeong and Hmelo-Silver, 2016). All these can be used as guidelines for *designing forms and supports* in terms of (a) pedagogical designs and (b) technological tools for CSCL to overcome the interaction challenges and support critical CL processes. These can be enacted in advance to guide group activities—for example, during the groups' learning processes as a support for orienting to the productive collaboration or as a support for monitoring learning and interaction during the collaboration process.

Collaboration scripts are pedagogical designs of scaffolding that pre-structure socio-cognitive processes of CSCL. They define phases and tasks for students to perform, group composition, task distribution, roles of the group members, the mode and granularity of interaction, and timing and social levels of phases (Dillenbourg and Hong, 2008). Computer support in scripting can also mean that they are implemented in the interfaces of CSCL environments (e.g., prompts), aiming to facilitate cognitive, metacognitive and social activities of learners. CSCL scripts have been found to have some effect on domain learning but a significant effect on collaboration skills (Vogel et al., 2017). For example, prior studies have explored how scripting can be used as a support for learning through argumentation and how argumentation skills can be supported with scripting (Noroozi et al., 2012). Although there are studies showing that scripting CSCL enhances learning, some criticism has also been leveled at this practice: whether overscripting hinders interactions and learners' agency and has only a weak effect on transfer of skills, and thus subsequently undermines learners' motivation (Radkowsch et al., 2020). An alternative view is not to constrain activity during collaboration, but instead to emphasize the planning and monitoring of collaborative interactions before, during and after it. *Orchestration* refers to the management of teaching in the classroom context, particularly from the perspective of the coordination of activities such as individual work, small-group interaction and classroom discussions (Tchounikine, 2013). Teachers orchestrate, monitor and guide CSCL activities among peer learners. Other key components of orchestration cover materials or resources for collaboration and the technology environment with its variety of tools for working with knowledge and sharing it. The cornerstone of pedagogically designing CSCL environments is to find a delicate balance between free-form collaboration and the structuring, scaffolding, and orchestrating of collaborative activities.

Efforts have been made to implement technologies *supporting collaborative knowledge construction*. One of the first approaches was the development of knowledge building competences supported by the CSILE (Computer Supported Intentional learning Environment) and Knowledge Forum learning environments (Scardamalia and Bereiter, 1994). Cognitive group awareness tools, in turn, have been implemented to make group participants aware of each other's knowledge and opinions, for example, by subjective ratings or multiple choice knowledge tests (Sangin et al., 2011). The cognitive group awareness tools have shown positive effects on knowledge construction because comparisons of participating group members' knowledge, opinions, and understanding are available and trigger discussion and shared meaning making (Kirschner et al., 2015). Sociability tools have been developed for helping groups to increase sound social space, trust, and sense of community, and to overcome challenges in socioemotional interaction. For example, Kreijns et al. (2013) suggested that a sound social space is the key to allowing group members using CSCL to gain feelings of relatedness, group cohesiveness, trust, and respect for each other.

Because metacognition plays an important role in group learning, recent technologies have focused specifically on *supporting metacognition* in the context of CSCL (e.g., Bannert et al., 2015). The support is not only in individual metacognitive processes, but rather to raise groups' metacognitive awareness in terms of shared regulatory activities, such as planning, task performance, monitoring and reflection. Typically, the support has been provided in the form of scripts or prompts that are used to facilitate learners' awareness of their metacognitive processes at individual and group levels (Janssen and Bodemer, 2013). All share the common goal of designing supports that (1) increases learners' awareness of their own and others' learning process, (2) externalize students' and others' learning processes in a social plane and helps in sharing and interaction, and (3) prompts the acquisition and activation of regulatory processes (Järvelä et al., 2015).

Learning analytics innovations hold the promise of empowering teachers and learners by making certain aspects of learning interactions visible and by providing information that can prompt CSCL. Real time analytics tools and dashboards have been developed that can provide information about group participation and task progress, the current state of the CSCL script, inform teachers about student progress and support learners (Martinez-Maldonado, 2019). Learning analytics techniques could be a key to increasing learners' agency and supporting self- and socially shared regulation of learning.

Future perspectives

CSCL is well established in education and work-life and increasingly implemented in various interdisciplinary group contexts. Rapidly developing technologies offer opportunities for participation, new forms for interacting, and spaces for social construction of knowledge and social relations.

The traditional focus in CSCL has been on specialized applications designed to support collaboration, while more recent younger generation digital ecologies—for example, generic social media services and games (Martin et al., 2020)—are not designed with the critical processes of productive collaboration in mind but rather have a strong emphasis on social relations for their own sake. CSCL research could put more effort into investigating social networking and large-scale learning environments, not only collaborative learning environments and tools of own designs. Today's learning environments also increasingly integrate physical and virtual learning spaces, formal and informal learning contexts, and global and local settings. Understanding how learning occurs and how learning could be supported in these contexts provides new avenues for CSCL research. In the future, CSCL will be considered more and more within global contexts, contributing to educational change and ongoing learning opportunities.

While contexts and perspectives in CSCL have broadened, multidisciplinary efforts have emerged to understand collaborative learning processes, renew theoretical concepts, and find new and complementary methodological and analytical solutions for researching CSCL (Dindar et al., 2020). For example, physiological measures and eye tracking have helped capture core processes in collaboration, such as affective activation or joint visual attention (Törmänen et al., 2021). In addition, sociometric badges and social network analyses have opened up new ways to capture the traces of social interactions, levels of explanations for interactions and how collaborators are connected to each other through physical or conceptual closeness (Zhou et al., 2020).

Increasing methodological opportunities have produced rich datasets. CSCL generates digital learning traces, and in multidisciplinary collaboration, this type of data can be analyzed—for example, by experts in learning analytics and machine learning—to make predictions and build causal explanations of how certain processes that make collaborative learning productive occur in interactions. Even with innovative future methodological perspectives, the need for detailed qualitative analyses in CSCL research, such as video analyses, remains essential since they are able to explain the reactions, regularities and nuances of human collaborative learning and, thus, contribute to strong evidence-based CSCL designs.

For decades, researchers, practitioners, and policy-makers have recognized the educational potential of students working with their peers in small groups to solve problems, complete tasks, and learn material. A large research base supports this enthusiasm. When compared with other instructional approaches such as whole-class or individualistic learning, peer-led group work has been shown to lead to higher student achievement, more positive attitudes toward learning and toward others, improved social skills, and increased perceptions of their own competence (e.g., [Slavin and Lake, 2008](#); [Kyndt et al., 2013](#)). The positive effects may be immediate, delayed, or both (e.g., [Howe et al., 2005](#)).

Peer-based learning approaches have been described in multiple ways, often in terms of cooperative and collaborative learning. Although the origins of cooperative and collaborative learning are different in many respects (for example, the former is often seen as more structured in terms of incentives and rewards, task design, role assignment, and group membership to foster positive interdependence among group members and individual accountability for one's own learning), the terms are often used interchangeably. In this article, we do not distinguish between them, but consider both under the umbrella of instructional approaches that provide students opportunities to learn from each other as they work together in face-to-face small groups.

The article "Peer learning in the classroom" in the third edition of the *International Encyclopedia of Education* ([Webb, 2010](#)) explored the mechanisms by which working with other students is thought to benefit student learning, and the many ways in which small-group work might be orchestrated to engender the learning benefits. This article focuses on research developments and directions that have appeared since then, particularly involving the links between student interaction during group work and learning outcomes, and the ways in which teacher practice can support productive group functioning.

Theoretical justification for the benefits for learning: the cognitive elaboration perspective

The cognitive elaboration perspective focuses on how overt communication processes during collaboration may trigger internal cognitive processes that are associated with learning. During group collaboration, students may explain their ideas to others in the context of conveying information about how to solve a problem or complete a task, helping others understand the material, justifying their suggestions in response to challenges, questions, or disagreements, or challenging others when perceiving conflicts or discrepancies. Students may engage with others' ideas in the context of constructing or elaborating solutions to problems or tasks, comparing perspectives, or addressing differences in opinions or problem-solving strategies.

Explaining ideas to others, whether in the context of making suggestions or responding to others' questions and challenges, encourages students to reflect on and monitor their own thinking. In the process of transforming what they know into communication that is relevant, coherent, and complete so that others can understand it, students may recognize their own misconceptions, or contradictions or incompleteness in their ideas ([Benware and Deci, 1984](#)). To resolve these issues, explainers may bring concepts or details together in ways they had not thought of previously, may see ways to make their arguments more compact, their ideas clearer or more elaborated, or their problem-solving strategies more efficient, or may seek out and use new information to build more complete or correct conceptions ([Bargh and Schul, 1980](#); [Coleman et al., 1997](#); [King, 1992](#); [Palincsar et al., 1993](#)).

Similarly, engaging with others' ideas can lead students to revisit or re-examine their own ideas, make connections between their own and others' ideas, generate new ideas that combine or extend those already proposed, and actively search for more information to resolve inconsistencies between students' perspectives ([Brown et al., 1992](#); [Roscoe and Chi, 2008](#); [Wittrock, 1990](#)). As a result, students may develop fuller conceptions of ideas, deeper understanding of material, and new perspectives.

Example instructional programs

Multiple instructional programs have been designed to promote productive communication in cooperative and collaborative groups. In many of them, teachers set ground rules for student interaction and provide instruction and practice in communication skills. To increase group reasoning (jointly analyzing problems, comparing possible explanations, making joint decisions), teachers in a set of studies conducted by Mercer and colleagues set ground rules for Exploratory Talk to help students engage critically and constructively with each other's ideas. Students are expected to share all relevant suggestions and information, provide reasons to justify assertions, opinions, and suggestions, ask others to give reasons for their suggestions, listen to others attentively, discussing alternatives before making decisions, and accept and respond to constructive challenges (Mercer, 1996, 2000; Mercer et al., 2004; Rojas-Drummond and Mercer, 2003).

Preparation in communications skills is also a central feature of the SPRinG (Social Pedagogic Research into Group work) program developed by Baines et al. (2008); see also Baines et al. (2007), Blatchford et al. (2006) to help teachers create inclusive and supportive classrooms. Teachers use a variety of activities in classrooms in order to develop students' skills in the following areas: taking turns speaking; engaging in active listening; asking and answering questions; making and asking for suggestions; expressing and requesting ideas and opinions; brainstorming suggestions, ideas and opinions; giving and asking for help; giving and asking for explanations; explaining and evaluating ideas; arguing and counter-arguing; using persuasive talk; and summarizing conversations. For example, students engage in debates and follow-up debriefing to help them understand what reasons are, the importance and benefits of giving reasons, and possible words to use when providing or requesting reasons.

In an approach to literature discussion called Collaborative Reasoning, students work in small groups to discuss a central question (or moral dilemma) raised by a story and argue for and against positions they take on the central question (Chinn et al., 2001). Students are taught how to support their positions with reasons, to challenge one another with counterarguments and evidence, and to weigh the pros and cons of their own and others' positions (Reznitskaya et al., 2009).

Training of students in communications skills is a prominent feature of many other studies as well. In Gillies and colleagues' research program (e.g., Gillies, 2003, 2004; Gillies et al., 2014), teachers train students to actively listen to each other, to provide constructive feedback for each other's suggestions and ideas, to answer each other's questions, to encourage all group members to contribute to the group task, to try to understand other group members' perspectives, to explore disagreements, and to monitor and evaluate the progress of the group. As another example, the teachers in Veenman et al.'s (2005) study trained students in explanation-giving and help-seeking skills (e.g., giving explanations rather than answers, asking clear and precise questions).

These instructional approaches have been shown to increase the depth of group discussion and, often, group performance and/or student achievement. Some examples of positive outcomes include a higher incidence of detailed explanations when students jointly construct new knowledge or conceptions and resolve conflicting points of view, improved argumentation skills, higher reasoning scores, and higher achievement in multiple subject matters, including social studies, mathematics, science, reading, and English than in programs without a strong focus on productive cooperative or collaborative group work.

Process-outcome links: empirical evidence

Considerable evidence of the links between student interaction during group work and learning outcomes (e.g., in mathematics, science, educational psychology) comes from research that collects observational data about students' collaboration. Some studies have found that composites of communication skills—such as giving help with explanations and challenging others' suggestions with explanations and justifications (Veenman et al., 2005) or explaining one's own ideas and engaging with others' ideas (Ing et al., 2015)—significantly predict achievement. Other research has shown that specific communication dimensions, such as explaining (or justifying) one's own ideas, extending others' ideas, supporting others' arguments, rebutting others' suggestions, co-constructing reasoning with others, resolving conflicts with others using justification, and referring to and building on others' ideas by clarifying, correcting, completing, or extending the ideas (transactive communication), also significantly correlate with learning outcomes (Chinn et al., 2000; Howe et al., 2007; Jurkowski and Hanze, 2015; Van Boxtel et al., 2000; Webb et al., 2014).

Additional evidence of the benefits of certain kinds of engagement with others' ideas comes from studies of argumentation. Certain types of argumentation have been shown to be more effective than others in promoting conceptual gains in science understanding. For example, Asterhan and Schwarz (2007, 2009) showed that dyads who argued for and against competing solutions or positions (including explanations of pros and cons of them, sometimes called dialectical argumentation) showed greater gains than dyads who discussed only one proposed solution or position (one-sided argumentation). An important feature of dialectical argumentation is the attempt by group members to persuade each other of the merits of their held positions.

The importance of collaborative groups considering multiple ideas finds support in the work of Howe and colleagues (e.g., Howe and Zachariou, 2019) showing that discussing contrasting ideas is associated with greater conceptual understanding of science concepts. In particular, they found that exchanging and negotiating different opinions about solutions to science problems and discussing divergent views about science concepts were both positively associated with growth from pretest to posttest. In contrast, the more frequently groups engaged in discussion that confirmed one particular solution or perspective, the less they progressed.

Another way of conceptualizing communication in collaborative groups is the rank-ordered classification of engagement activity proposed by Chi and Menekse (2015). Their ICAP (interactive-constructive-active-passive) framework distinguishes between

ordered categories of engagement: (1) interactive and constructive engagement (students build on each other's contributions), (2) constructive without interacting engagement (students build on their own ideas without considering or extending others' ideas), (3) active engagement (students restate or repeat what was said), and (4) passive engagement (students listen without saying much). Their empirical studies show level of engagement of the dialog pattern to be significantly correlated with learning gains (see also Chi and Wylie, 2014).

Finally, some research has shown in-the-moment advances in learning that occur while students work on a task together. Roscoe and Chi (2008), for example, described how students trying to explain to another student the structure and functioning of the human eye realized or admitted that they did not fully understand. These realizations prompted students to revisit and review material, and to rethink their ideas in order to provide more complete and correct explanations. Brown et al. (1992) illustrate how the group's challenge of an explainer's incomplete or incorrect ideas caused the explainer to re-examine her prior knowledge, to formulate and test predictions based on her incorrect mental model, and to revise her ideas based on the information that her peers provided in response to her initial predictions (in this case, her ideas about animals' use of camouflage as a defense mechanism). Webb et al. (2021) showed how students made advances in their mathematical thinking (e.g., moving from strategies that were incomplete or partially formed, ambiguous, or invalid to strategies that were fully correct, complete, and unambiguous, generating new mathematical ideas, making connections to new mathematical representations, generating new and substantially different strategies) through the process of explaining their own thinking and engaging with others' ideas. Students corrected or extended their mathematical thinking when issuing challenges or being challenged, while elaborating on or extending others' ideas, and when making connections between different ideas being presented.

Teacher interventions with collaborative groups to support productive interaction

When to intervene

Many cooperative learning researchers and theorists advise teachers to monitor small group progress and to intervene when groups fail to progress or appear to be functioning ineffectively, when no group member can answer the question, when students exhibit problems communicating with each other, when students dominate group work without allowing true dialog, when students are denied opportunities to participate or are not treated with respect, and when students and/or their ideas are marginalized (e.g., Cohen, 1994; Ding et al., 2007; Johnson and Johnson, 2008). Similarly, Tolmie et al. (2005) also suggested that teacher guidance may help counteract students' tendencies to control group work or to disagree in unproductive ways (e.g., failing to provide reasons for their opinions and ideas), as well as enable children to explore ideas more effectively.

Should teachers always intervene when groups are off task? A recent study suggests it may depend on when the off-task activity takes place and how long it lasts (Langer-Osuna et al., 2020). Brief off-task activity that takes place at the beginning of a group's collaboration may serve to help students ease into the task (for example, quick remarks about interesting features of the task may reorient group members toward each other and facilitate the start of the task). Off-task activity that occurs in the middle of group conversations may serve to help certain students gain access (or re-access) to the conversation (for example, a previously ignored student was able to secure entry into the group collaboration by engaging in brief, off-task use of materials that drew others' attention and interaction). Off-task activity that lasts longer than a minute or so, however, might signal that a group is avoiding the task, which may warrant teacher intervention.

Should teachers always intervene when some students appear to dominate the conversation at the expense of other students' participation? Esmonde (2009) showed that students who positioned themselves as experts (and were granted this authority by other group members) tended to dominate interactions and have the most opportunities to explain their thinking and obtain feedback from peers. Students positioned as novices, on the other hand, tended to be excluded and have fewer opportunities to express their ideas. However, Shah and Lewis (2019) found that participatory equity, in which opportunities to participate are fairly distributed among group members, is fluid, not static, such that levels of inequity fluctuate over the course of the collaboration. Even collaborations in which one student generally dominates the work may nonetheless exhibit equitable participation at times, and vice versa. Furthermore, different factors may drive inequity, including a push to finish the group's work as quickly as possible, group members' interpretation of their relational role as the person in charge, or group members' perceptions that others may lack relevant knowledge or competence. These results show that teachers need to be vigilant about monitoring group work, to consider both short-term and long-term participation patterns among group members, and to take into account the multiple reasons why inequitable participation might arise.

How to intervene

Content versus process teacher interventions

Some research has considered whether teachers should intervene about content or about process, and the results are not clear cut. Some evidence suggests that process interventions may be more productive than content interventions. For example, in a comparative study by Dekker and Elshout-Mohr (2004), students in classrooms in which teachers were instructed to provide only process help to groups (e.g., encouraging students to explain and justify their work) engaged in more extensive discussions and exhibited more equal participation among group members, and showed higher mathematics posttest scores, than students in classrooms in which teachers were instructed to provide only content help (e.g., giving hints about the mathematical content and strategies).

Other work suggests that content help may sometimes be effective, depending on how explicit or direct it is. Chiu (2004) found that more-explicit teacher help (e.g., explaining a concept, or giving a solution tactic) reduced groups' subsequent time-on-task and the depth of their discussions (whether students provided new ideas and explanations) compared to less-explicit teacher help (e.g., drawing attention to an aspect of the problem through asking questions instead of providing a solution strategy or telling groups how to proceed). Gillies (2004) found similar results: students in classrooms in which teachers provided direct instruction and explicit content help provided fewer detailed explanations than students in classrooms in which teachers provided less-direct content help (e.g., asking open and tentative questions to probe, clarify, and focus student thinking). In a further refinement, Meloth and Deering (1999) reported that teacher explicit content help (e.g., providing direct instruction about content) facilitated productive group discussion (in terms of students communicating their ideas and supporting their ideas with explanations and elaborations) when the teacher listened to the group's ideas (for example, to find out whether groups were focusing on irrelevant information) before providing specific instruction, but had no effect on group discussion otherwise. When the teacher's content help did not relate to a group's discussion, groups were able to disregard the teacher's suggestions without reducing the quality of their conversations.

More important than the focus of teacher interventions—subject matter content or group process—may be whether teachers try to ascertain student thinking and base their interaction on what they learn about students' thinking on the task (see Cohen's 1994 caution for teachers to carefully listen to group discussions, and to make hypotheses about the groups' difficulties before deciding on what questions to ask or suggestions to make). Interestingly, Chiu (2004) observed that attending to students' thinking may influence the nature of teacher interventions with groups. Specifically, teachers who considered and evaluated students' suggestions tended to provide less-explicit help and issued few directives; teachers who did not evaluate groups' ideas tended to give more-explicit help and issue many directives. Considering and evaluating strategies that groups were using made it possible for teachers to work with students' ideas and to help in less direct ways, such as asking students to formulate a plan for answering part of a problem that the group had not yet addressed, or asking students to reread a part of the problem that they had misinterpreted.

Specific teacher discourse moves with small groups

Teachers can use specific discourse moves when intervening with small groups to improve group functioning and students' learning outcomes. For example, in Collaborative Reasoning (described above; Chinn et al., 2001), to spur students to generate different reasons for their positions and participate in counterarguments, and to weigh the pros and cons of their own and others' positions when discussing moral dilemmas, the teacher asks students to clarify their ideas, prompts them to give reasons or evidence for their positions, and encourages them to respond to each other's claims. These teacher moves support rich student discussions which in turn increase students' argumentation skills (as measured by posttest reflective essays on new topics; Reznitskaya et al., 2009).

Additional teacher moves shown to be productive include asking students probing and clarifying questions ("Can you tell me a little more about what you're intending to do here?"), acknowledging and validating students' ideas ("I can see you've worked really hard to find out how these items are related. I wonder what you could do now to identify a key category they can all fit into?"), identifying discrepancies in students' work and clarifying options they may take ("I wonder how you can include ... when you've already mentioned ... ?"), and offering suggestions in a tentative fashion ("I wonder if you've considered doing it this way?"; Gillies, 2004, p. 260). Such moves encourage students to acknowledge each other's ideas, expand on others' suggestions, challenge others' ideas, and probe each other's opinions, which, in turn, lead to achievement gains (improved scores on posttests of reasoning and problem solving; e.g., Gillies, 2003, 2006; Gillies and Boyle, 2008).

Recent research distinguishing between initial teacher invitations for students to explain their thinking and engage with others' ideas and teacher follow up on those invitations shows that teachers' initial invitations may not be sufficient to produce in-depth student conversations and that follow up may be critical. Franke and colleagues (Franke et al., 2015; Webb et al., 2019) found that teachers' initial moves to invite student explaining such as pressing students to explain, clarify, and justify their problem-solving strategies, and initial moves to invite student engagement with others' ideas such as asking students to compare their strategies to those generated by others, explain problem-solving strategies that other students use, and ask questions of each other were not always effective. Students were more likely to produce complete explanations of their ideas when teachers continued to probe student thinking to prompt students to give further details about their problem-solving strategies beyond their initial explanation, and when teachers persisted in asking questions in order to push students to clarify the ambiguous aspects of their explanations. Similarly, students were more likely to go beyond superficial and perfunctory engagement with each other's ideas when teachers followed up with additional questions that drew attention to specific details in students' mathematical ideas and encouraged students to engage with those particular details ("Do you understand why she [divided each whole] into five pieces?").

The teacher discourse moves such as those described above can have delayed, as well as immediate, effects on collaborative group functioning. Jadallah et al. (2011) showed how teacher moves can propagate through students' discussions. In their study of collaborative reasoning about moral dilemmas and policy issues, when the teacher asked students to clarify their suggestions, not only did students generally do so, but there was a fairly high probability that other students would subsequently engage with the clarified idea of the first student. More specifically, when a student gave clarification in response to a teacher prompt to do so, there was a 41.9% probability that a second student would comment on the first student's ideas, and a 49.1% probability that a third student would also comment on the idea. After the teacher prompted a student to clarify an idea, long chains of conversational turns among students (e.g., 27 turns) were devoted to engaging with the initial clarified idea (including repeating details in the idea, elaborating on the idea, and challenging the idea). Other teacher moves found to have delayed positive effects on students' elaborations of their thinking (particularly the extent to which students explicitly conveyed connections between ideas) included

praising students' use of specific cognitive strategies (e.g., using examples in their explanations), and regulating students' turn-taking (e.g., by asking students who were interrupted by other students to continue talking; [Lin et al., 2015](#)).

The delayed effects of teacher moves can persist even when the teacher is no longer present with the group. For example, [Webb et al. \(2009\)](#) found that teacher probing of students' explanations to uncover details or further thinking about problem-solving strategies often corresponded with students giving more details about their strategies during their discussions (and often providing complete explanations) after the teacher intervened and had departed from the group than they had offered before the teacher intervened.

One reason for the sustained effects of teacher moves such as prompting for clarification of ideas may be that the teacher's move lends credence to the idea and bestows intellectual authority on the student offering the idea. A teacher's attention to a particular student's idea may position the student as a credible source of information, with the result that the student's ideas gain special traction, attention, and positive evaluation during the group's discussion ([Langer-Osuna, 2016](#)).

Effects of teacher discourse in the whole class on small-group functioning

Teachers' discourse during whole-class instruction can also impact how students interact with each other in collaborative groups. A consistent theme is that teachers pressing students to explain their thinking during whole-class discussions is important for the depth of students' discussion in collaborative groups. In [Kazemi and Stipek's \(2001\)](#) "high press" classrooms, mathematics teachers pressed students to explain and to justify their problem-solving strategies during whole-class discussions. For example, a high-press teacher may have pressed students to further explain each step in their problem-solving procedures, to give mathematical arguments for their choices of strategies, to explain the significance of specific details in their strategies, and to demonstrate their problem-solving procedure in different ways (e.g., verbal description, shading diagrams, adding fractions). Some of the mathematics teachers in [Webb et al.'s \(2008, 2009\)](#) studies carried out similar moves, such as pushing students to make explicit the steps in their mental processes both when students' answers and strategies were correct and when they were incorrect. "High press" teachers make analogous moves in other subject matter domains as well. For example, teachers of literature interpretation in [Smagorinsky and Fly's \(1993\)](#) study invited students to participate in interpreting text and prompted them to elaborate on their responses (e.g., by directly requesting elaboration, repeating portions of students' suggestions in the form of questions).

In contrast, teachers in "low press" classrooms tend not to ask students to explain their thinking during whole-class discussions. They might ask students to describe the steps they used to solve problems but not ask students to link their strategies to mathematical reasons or to explain why they chose particular procedures, and may accept students' correct answers and procedures without follow-up ([Kazemi and Stipek, 2001](#)). Or they might generally accept the first explanations students offer even if they are incomplete or incorrect ([Webb et al., 2008, 2009](#)), request only answers, or ask students to provide just the results of calculations that the teacher set up, without asking students to explain their reasoning ([Webb et al., 2006](#)). Or, in the case of literature interpretation, teachers may assume responsibility for interpreting the text without asking students to contribute ([Smagorinsky and Fly, 1993](#)).

The differences between teachers' discourse during their whole-class instruction in high-press and low-press classrooms have been shown to correspond to differences in student-led peer interaction. In collaborative group work in "high press" classrooms, students use mathematical arguments to explain why and how their solutions work, provide explanations that are correct and complete, strive to arrive at mutual understandings of solutions, and, in the case of literature interpretation, elaborate on their ideas for how to generalize from the text, and frequently ask each other to explain their reasoning. In contrast, in collaborative group work in "low press" classrooms, students summarize, but do not explain, their steps for solving problems, do not debate the mathematics involved in the problems, and rarely ask about their peers' thinking or strategies, and, in the case of literature interpretation, give brief summaries of the text without elaborating on their suggestions.

Additional insights into specific moves teachers make during whole-class discussions to encourage students to engage with others' ideas that may transfer to student behavior during collaborative work come from a recent case study by [Webb et al. \(2018, pp. 300–301\)](#). First, the teacher enacted a variety of ways of engaging with students' ideas, including asking students specific questions about details in their problem-solving strategies, restating or rephrasing students' suggestions, noting similarities and differences between different students' ideas, challenging students' suggestions, adding on to students' ideas, and drawing connections between students' ideas. Second, the teacher supported students to engage with others' ideas by explicitly calling for students to engage with others' ideas in the ways she had modeled, such as making connections between different students' ideas ("Can you see any connections between the red strategy and the blue strategy?"), and asking them to consider particular details in a student's strategy ("Are you sure about this part [of the student's strategy]? Can you talk about how it's going to work?"). In many cases, she gave them specific guidance in what to ask or what to say, for example, when revocing another student's idea ("Can you talk about what was the first step that these partners took together? [Say] 'First, these partners ...'"') or when challenging another student ("If you disagree [say] 'I'm disagreeing because ...'"). In their collaborative groups, students carried out all of the ways of engaging with each other's ideas that the teacher had enacted herself or had supported students to carry out during whole-class instruction, including using some of the same language the teacher had used or suggested (e.g., "Why do you think that?", "Where did you get the 5 from?" "So you're saying we could do another 4 times 12.").

Conclusion

Over the past several decades, research has deepened our understanding of the kinds of communication in cooperative and collaborative groups that are productive for student learning, and has heightened our awareness into how teachers can intervene with groups to support productive group functioning. A predominant theme from recent research results is that teachers pressing students to clarify and elaborate on their own and others' thinking can have positive influences on group conversations that are both immediate and delayed. Moreover, analogous teacher moves with students during whole-class discussions can carry over to interaction among students in collaborative groups.

An intriguing possibility is that productive in-the-moment teacher discourse with cooperative and collaborative groups may complement other ways in which teachers can prepare students to work collaboratively. As described in the article "Peer learning in the classroom" in the third edition of this encyclopedia, to support group functioning teachers can, for example, provide students with instruction in communications skills, structure group interaction by assigning cognitive roles or by giving students high-level questions to ask each other, and pose open-ended tasks that invite multiple perspectives or require multiple areas of expertise. Future research will reveal how teachers may be able to use intervention strategies in tandem with these other supports to produce fruitful interaction in cooperative and collaborative groups and, hence, positive student learning outcomes.

Questions of definition

"Dialogic" combines the Greek word "dia" meaning "through or across" with the Greek word "logic" meaning pertaining to words and speech but also, perhaps most relevantly here, pertaining to reason. From these roots the word "dialogic" can be seen as referring to "reason across difference". The term dialogic was first used to refer to novels in the form of a dialogue. The philosopher Michael Bakhtin extended this meaning to refer to novels, such as those of Dostoevsky, where multiple characters interact with different points of view which are not reduced to a single reality. For Bakhtin and the Bakhtin circle, dialogism was extended beyond literature to become a general theory of meaning. Meaning is not contained by words and utterances but is found only in the dialogue between them and their context. The meaning of what is said in a dialogue is a response to things that have been said before and an anticipation of things that will be said in response. One implication of this is that wherever there is meaning there is more than one voice in play. Another implication is that there are no final meanings, only an ongoing open dialogue. Dialogic is a contrast to monologic or the view that there is a single correct voice or final view of things.

Dialogic education uses dialogue between students and between teachers and students with the goal that students learn how to engage more effectively in dialogue both as a way of learning and as a way of thinking. We are using dialogic education here as an umbrella term for the various traditions that we think fit, at least in part, our definition, including dialogic teaching (Alexander, 2008), dialogic learning (Flecha, 2000), thinking together (Mercer and Littleton, 2007), accountable talk (Michaels et al., 2008), and dialogic pedagogy (Matusov, 2009).

Traditions of dialogic education have been divided according to whether they are more epistemological or more ontological (Matusov, 2009; Wegerif et al., 2019; Kim and Wilkinson, 2019). Epistemological dialogic education focuses on knowledge construction and ontological dialogical education focuses on changing self, society and experienced reality in the direction of becoming more dialogic or dialogical (where dialogic and dialogical are synonyms). In practice, this epistemological/ontological theory divide tends to correspond with a "talk only" versus "dialogue more generally" divide. Where the focus is only on teaching a way of talking then the theory focus tends to be on shared knowledge construction, whereas if the practice extends beyond talk to include multi-media and embodied position taking perhaps through music, dance or drama then, whether this is implicit or explicit, the education programmes are likely to aim at increasing dialogicality as a way of being in the world and not just as a way of knowing.

Epistemological dialogic education: constructing knowledge together

Dialogic or dialogism refers to a theory of how we make meaning and construct knowledge (Linell, 2009; Wells, 1999). It starts with the claim that all meaning for us arises first as an answer to questions that we ask explicitly or implicitly within dialogues. In this respect, the meaning of utterances and other signs can only be understood in context. A word someone uses in a dialogue does not necessarily have the same meaning as the same word in the dictionary; its meaning is given through its position and role in the dialogue as a response to what has been said as an attempt to influence what will be said (Linell, 2009; Rommetveit, 1992). The big epistemological implication of this is that to understand the meaning of any sign or utterance we have to look at the context, especially the historical context, and be aware that there is always more than one relevant voice or perspective in play. The big educational or pedagogical implication is that, since knowledge is always dialogic, we should not teach facts without context but need to teach students how to construct knowledge and make sense of knowledge by teaching them how to engage in dialogue and how to understand the historical and evolving nature of knowledge.

This epistemological focus can be found in most approaches to dialogic education, such as Alexander's (2008) dialogic teaching (2008), Lipman's (2003) community of enquiry, Littleton and Mercer's (2013) exploratory talk, and Michaels et al.'s (2008) accountable talk.

Ontological dialogic education: new selves and new worlds

The above epistemological conception of dialogic education is close to constructivism, or, more specifically, social constructivism (Bereiter, 2005; Paavola and Hakkarainen, 2009), insofar as both dialogic education and social constructivism understand meaning or knowledge to be constructed socially. However, dialogic education differs from constructivist approaches to education in its ontological understanding: it places less emphasis on the knowledge that is constructed than on the relationships and spaces of dialogue opened up by the differences between perspectives (Wegerif, 2007). One aim of a more ontological understanding of dialogic is the expansion of dialogue or dialogue as an end in itself within the curriculum.

Different strands of the ontological conception of dialogic education focus variously on understanding and transforming (a) the self, (b) social and political reality or (c) experienced reality as a whole.

- (a) One strand of ontological dialogic education focuses on developing the self as a more dialogic author (Matusov, 2009; Sidorkin, 1999). Through dialogic education, students are more open to embracing and learning through differences and better at engaging in dialogue, thinking, and holding multiple perspectives together in reflective tension (Wegerif, 2007, 2013).
- (b) Freire (2005) proposed dialogic teaching as a way to change the social and political reality in the direction of greater social justice. Dialogic education, in this model, is a form of critical education. Whereas monologic education or what Freire referred to as the banking model, deposits fixed truths in the heads of students and so does not change the social order, dialogic education invites students to question and to name the world afresh for themselves.
- (c) Another strand of the ontological conception of dialogic education emphasizes understanding and transforming experienced reality as a whole. It considers education as a journey of development from monologic to dialogic. This journey begins with the monologic illusion that selves and objects are separate entities within an external fixed reality and moves toward the dialogic realization that all identities are aspects of a universal dialogue—multiple, chiasmic and co-constructed—with which people can learn to engage more reflectively through education (Wegerif, 2007; Kennedy, 2014).

Epistemological dialogic education and ontological dialogic education are not incompatible. In practice, it is common for dialogic approaches to engage students in an ongoing process of shared enquiry as a way to gain knowledge (i.e., epistemological) with an additional focus on developing a dialogic orientation to expand dialogue as a valued end in itself (i.e., ontological). For examples of the combination of epistemological with ontological dialogic education see Nystrand et al. (1997), Flecha (2000), Lefstein and Snell (2013), and Phillipson and Wegerif (2017). Given that there are already many terms for collaborative learning and social constructivist pedagogy, it could be argued that the use of the term dialogic education should be reserved for educational approaches in which there is an ontological as well as an epistemological dimension in that dialogue is being promoted and expanded as an end in itself as well as a means to knowledge construction.

The historical origins of dialogic education

The importance of dialogue and dialogic reasoning to education has roots deeper and broader than the Western enlightenment. Evidence of both dialogic educational practices and recognition of the educational value of dialogue can be found in non-Western thinking much earlier than the enlightenment. In the *Analects*, for example, Confucius encourages his students to interpret, persuade, and reason through dialogue (Li and Wegerif, 2014). The notion of "forming circles of learning" where different views are discussed together can be found in the traditional Islamic approach to education (Makdisi, 1990, p. 210), along with traditional Jewish education (Schwarz and Baker, 2016) and Indian Buddhist intellectual traditions (Sen, 2005).

Socrates' contrast between "living" and "dead" meaning

Some writers replace the word dialogue with "talk" preferring, for example, to write about research on classroom talk rather than classroom dialogue (Mercer, 2010). However, not all talk is dialogic. Barnes, one of the earliest researchers of classroom talk, distinguishes between "presentational talk" which is not dialogic and "exploratory talk" which is (1976). Exploratory talk is distinguished by the fact that thinking is visible in the talk as Barnes puts it. This theme can be traced back to the ancient Greek philosopher Socrates, who taught his students orally, through questioning. The technology of alphabetic writing was spreading to Greece in Socrates' lifetime. As recorded by Plato, Socrates questions the cognitive value of writing and claims that real intelligence exists only in verbal dialogue, not in written texts. He argues that words spoken in dialogue are "living", capable of answering back and defending themselves, whereas written words are dried up and "dead" like seeds left in the sun or orphans with no-one to defend them (Plato, 360 BCE). Of course, later writers like Bakhtin managed to show that written words too could be living dialogic words but nonetheless the important contrast Socrates drew between living and dead words is the essence of the dialogic versus monologic distinction taken up by all dialogic theorists.

Buber's philosophy of dialogue

Writing in Germany in the 1930s before the second World War, Jewish philosopher Buber (1958) distinguishes between an objectifying orientation ("I-it") and an inter-subjective orientation ("I-thou"). The "I-it" orientation locates and defines things externally with the monologic assumption of a single true perspective. The "I-thou" orientation enters into a responsive dialogue in which the perspective of the other or interlocutor is taken seriously. Interestingly, Buber's concept of the other includes nature, trees and dogs, and God in the form of the "eternal Thou". Buber is not saying that these are to be thought of as separate responsive consciousnesses but that dialogue is best thought of as an orientation that opens a shared space into which we can enter rather than a relationship between separate entities exchanging words or other tokens. Buber (1958) writes of the space "in-between", or the "space of meeting", thus perhaps first introducing the theme of dialogic space, found in dialogic education today (e.g., Yang, 2016; Wegerif, 2008; Mercer et al., 2010).

Bakhtin's dialogism

In his theory of dialogism, Bakhtin (1981, 1986), an influential point of reference for contemporary dialogic education, develops Socrates' and Buber's accounts of the essential dialogic distinction between the space inside dialogue and the space outside; the living voice of the act of saying and the dead voice of that which has been said. At one point he conceptualizes this distinction in terms of the difference between the authoritative voice he associates with schoolteachers and the persuasive voices he associates with peers. The authoritative voice keeps people outside the dialogue in an isolated and static condition; they cannot enter the dialogue but must simply accept or reject it. Therefore, the dialogue terminates without generating any newly constructed knowledge or perspectives. In contrast, the persuasive voice embeds people in the dialogue, being both inside the dialogue for interanimation and outside the dialogue for reflection. Bakhtin (1981) commends the persuasive voice for its ability to awaken new and independent voices productively and creatively and make the dialogue move forward. Applied to education, this essential dialogic distinction implies that the authoritative transmission of knowledge may reduce the diversity of voices and fail to promote deeper understanding. Students can learn more effectively if they are called into and able to locate themselves both within and outside persuasive dialogues to engage with and adopt different points of view.

Bakhtin (1986) emphasizes the potentially infinite nature of meaning in dialogues. Within persuasive dialogues, there are always more perspectives, pulling in different directions, that can be inter-animated, thought with, and incarnated. This resonates with Kristeva's (1966) claim, building on Bakhtin, that there is always "intertextuality" between dialogues.

Freire's pedagogy of the oppressed

Freire (2005), a Brazilian educator, explicitly argues for the social significance of dialogic education in his book *Pedagogy of the Oppressed*. He criticizes conventional education as following a "banking" model and thus oppressing students through manipulation, because it treats knowledge as fixed facts to be inserted into the minds of students. In contrast, according to Freire, dialogic education is about empowering students to speak their own words so that they can name the world in their own ways. In doing so, both an expansion of consciousness and a transformation of social reality can occur. According to some critics, this view may itself be considered manipulative (Matusov, 2009), because the criteria determining what counts as social justice are pre-established rather than dialogically constructed. Regardless of its political implications, however, Freire's account of the empowerment of students implies that dialogic teaching and learning should be based on the mutual respect and collaboration of teachers and students and designed to promote students' voices and responses rather than rendering them merely knowledge receivers. This is one of the key values of dialogic education. In addition, Freire's focus on liberating and empowering students to participate equally and collectively in dialogues that shape a shared social reality reflects a key objective of dialogic education.

Some contemporary approaches to dialogic education

From the above theoretical avenues, we can see that dialogic teaching and learning take place through opening the dialogic space, in which different perspectives can inter-animate and inter-illuminate each other for conceptual understanding. This approach not only offers a way to teach “for intelligence” but also indicates a more explicit purpose: education “for dialogues” (Resnick and Schantz, 2015). Contemporary dialogic approaches to education are, either explicitly or implicitly, designed to open up and expand dialogic spaces in which (1) knowledge can be co-constructed; (2) dialogic orientations, characterized by an openness to the possibility of learning from others and from otherness, can be promoted; (3) and social norms that support productive and reflective dialogue can be mutually developed.

This section outlines several contemporary dialogic models, approaches and frameworks with different foci in different contexts and outlines research evidence as to the impact of dialogic education.

Nystrand's dialogically organized instruction

Informed by Bakhtin's dialogism (1981, 1986), Nystrand and his colleagues investigated hundreds of English lessons in American secondary education, from which they synthesize and extract signs and features of effective teaching in classrooms. Based on their analysis, they suggest that the potential of language for conceptual understanding depends largely on how utterances are treated within instruction; that is, how teachers organize instruction (Nystrand et al., 1997). Hence, they propose a dialogic form of instruction, characterized by respecting and giving space to students' voices, which they call “dialogically organized instruction” (Nystrand et al., 1997).

In Nystrand's model of dialogically organized instruction, three “dialogue moves” frequently used by teachers to organize dialogic instruction are emphasized: uptake, authentic questions, and high-level evaluation. Uptake refers to the process of understanding the voices of students, allowing the teacher to validate particular students' ideas by incorporating their responses into subsequent questions (Nystrand et al., 1997). This reflects the role of the teacher in inter-connecting the voices of students and building on their contributions. Different from questions with pre-determined answers, authentic questions are designed to invite students' perspectives and ideas into educational dialogues, promoting teacher-student interactions. Similarly, high-level evaluation is opposite to low-level evaluation in which teachers respond to and assess students' ideas with simple repetition or perfunctory praise. Instead, high-level evaluation requires teachers to respond to students' ideas with elaboration, commentary, or follow-up questions (Nystrand et al., 1997). These three inter-related “dialogue moves” illustrate how teaching can be done dialogically to fuel students' understanding in classroom dialogues.

Mortimer and Scott's communicative approach

Through analysis of observed teaching episodes in science classrooms, Mortimer and Scott (2003) derive an analytical framework to characterize teacher-student discourses in science education. Within this framework, classroom discourses have two dimensions: dialogic–authoritative and interactive–noninteractive. The former refers to the extent to which teachers take into account students' ideas in the flow of discourse, whereas the latter represents the degree of teacher-student interaction (Mortimer and Scott, 2003). Combining these two dimensions, four types of teacher-student discourses are defined, as shown in Table 1.

Based on their empirical investigations in science classrooms, Mortimer and Scott (2003) argue that efficient teaching entails alternation between the four types of teacher-student discourse. Dialogic discourses (i.e., NI/D and I/D) suit the goal of engaging students in exploration of their pre-existing ideas about and experiences of scientific phenomena, whereas authoritative discourses (i.e., NI/A and I/A) fit the objective of introducing and focusing on the “scientific story” (e.g., the scientific meaning of concepts, Mortimer and Scott, 2003, p. 18).

Table 1 Types of teacher–student talk.

	<i>Non-interactive (NI)</i>	<i>Interactive (I)</i>
Authoritative (A)	NI/A: Monologic lecture	I/A: Recitation
Dialogic (D)	NI/D: Dialogic lecture, presenting various points of view	I/D: Discussion

(1) The NI/A type represents mere lecturing based on a monologic orientation, in which the teacher and students do not interact.

(2) The NI/D type can be considered as lecturing based on a dialogic orientation, in which the teacher and students do not take turns, but multiple voices and perspectives on educational content are valued and taken into account.

(3) The I/A type can be understood as recitation; although interaction occurs, different perspectives, including the voices of students, are not taken into account and attention is focused on a monologic perspective.

(4) The I/D type is dialogic discussion, in which interactions occur and different perspectives are taken into account (Mortimer and Scott, 2003).

This communicative approach implies that teachers have a repertoire of types of teacher-student discourse that they strategically deploy to suit educational purposes. This distinguishes it from Nystrand et al.'s (1997) idea that teachers should always be dialogic. One way to explain this tension is that the goal of introducing a "scientific story" can appear to some extent monologic; it requires students to learn the current consensus as to the scientific meanings of concepts. Authoritative discourse is more efficient for this than dialogue. Mortimer and Scott (2003) suggest that effective classroom discourse should follow a rhythm. In such a rhythm, the teacher-student discourses initially are dialogic, when the teacher explores students' ideas about scientific concepts. Subsequently, the discourses then shift toward a more authoritative mode as the teacher works on aspects of the scientific concepts "through shaping, selecting and marking ideas. Finally, the teacher synthesizes key points and reviews the students' progress. In other words, dialogic discourse calls for subsequent authoritative discourses in which the teacher intervenes to clarify the scientific perspective (Scott et al., 2007).

Alexander's dialogic teaching framework

Alexander offers a comprehensive framework for explicating dialogic teaching and supporting teachers who intend to improve the quality and power of educational dialogues. This framework is largely derived, he claims, from his comparative educational study on classroom discourses in English, Russian, American, Indian, and French primary education, underpinned by Bakhtin's (1981) dialogism and Vygotsky's (1978) socio-cultural theory. In the fieldwork for that comparative analysis, Alexander observed and interviewed teachers, students, and other stakeholders in the above mentioned five educational systems to explore their educational practices and how these practices related to the culture, policies, and structures of the different systems.

Within the framework, Alexander (2008, p. 185) defines dialogic teaching as a general pedagogical approach that "harnesses the power of talk to engage (students), stimulate and extend their thinking, and advance their learning and understanding," which can be characterized by a set of core principles and indicators. The principles are:

- Collectiveness: teachers and children address learning tasks together, whether as a group or as a class
- Reciprocity: teachers and children listen to each other, share ideas and consider alternative viewpoints
- Supportiveness: children articulate their ideas freely, without fear of embarrassment about "wrong" answers, and they help each other to reach a common understanding
- Cumulativeness: teachers and students build on their own and each other's ideas and chain them into coherent lines of thinking and enquiry
- Purposefulness: teachers design and steer classroom talk with specific educational goals in view

Similar to the communicative approach, Alexander's framework is based on the notion of a repertoire, requiring teachers to have a repertoire of methods of organizing interactions and engaging in discourse and to be able to strategically adopt different types of classroom discourse to achieve the goals of the curriculum. The types of classroom discourse include both teaching talk (e.g., exposition, rote, lecture) and learning talk. The latter enables students to explore, interpret and argue. Although this "repertoire" approach includes some monologic types of talks, it privileges discussion and dialogue, which stimulate students' thinking and advances their learning. For Alexander, discussion pursues the goals of information-sharing and problem-solving, whereas dialogue, as directed inquiry and guided questioning, can achieve a mutual understanding and scaffolding to foster independence. Alexander regards discussion and dialogue as "the forms of talk which are most in line with prevailing thinking on student's learning" (2008, p. 103) and "have by far the greatest cognitive potential" (2017, p. 31). This emphasis makes it more aligned with dialogically organized instruction (Nystrand et al., 1997), and distinct from the communicative approach (Mortimer and Scott, 2003).

Teaching the dialogue so far

The above three approaches share an epistemological position focusing on the power of discourse for knowledge co-construction. More recently, another approach to dialogic teaching has emerged, focusing on the ontological stance of dialogue. Grounded largely in Bakhtinian dialogism and Oakeshott's (1960) notion of education inducting students into "the conversation of mankind," and inspired by Langer's (2016) emphasis on the mindful learning of teaching everything from a range of perspectives and as emerging from debate, Phillipson and Wegerif (2017) argue that dialogic teaching is not just about constructing knowledge but is also about "teaching the dialogue so far." This builds on what Linell (2009) refers to as "double dialogic", that voices are not just in dialogue with each other but also with the cultural and historical context. In an educational dialogue in a classroom there is often engagement with a subject discipline which itself is a form of dialogue, albeit, a long-term cultural dialogue. Education involves inducting students into participation, through dialogue, in the long-term dialogue of culture which, although it has many strands, is ultimately one open-ended dialogue of humanity. Oakeshott (1960) refers to education in this sense as giving students access to their "inheritance."

The role of the teacher is not to transmit fixed and final knowledge but to summarize and present "the dialogue so far", so that latecomers can catch up (Phillipson and Wegerif, 2017). Knowledge should be presented in the ways in which it has previously been constructed, as a story about the dialogue that led to the "knowledge", the questions asked and how and why they were asked. The

significance of “teaching everything as fallible and dialogic” is to leave students free to build upon and reflect upon what they have been taught and to challenge and develop it in the future. In this way, “teaching the dialogue so far” enables students to challenge and develop it through participation in an ongoing and open-ended shared inquiry.

Accountable talk

The accountable talk approach places thinking at the core of the curriculum and emphasizes the primacy of talk in promoting thinking. The notion of “accountable talk” was originally abstract, introduced by Resnick (1999), Resnick and Hall (1998), but it was subsequently developed into a more concrete pedagogical approach (Resnick et al., 2010, 2018a,b). Talk is understood to promote learning and thinking when it is accountable to accurate knowledge, rigorous reasoning, and the learning community. “Accountability to knowledge” refers to the content of students’ discussion. As far as possible, they should argue based on specific and accurate information or solid evidence. From this perspective, students may challenge the evidence used by others within argument (e.g., “are those statistics accurate?”). Accountability to rigorous thinking is ensured when talk follows a logical and coherent line of argument from premises to conclusions. In other words, students must not only talk about talk but also talk about reasoning (e.g., “what’s your reasoning for that explanation?”). Accountability to the learning community is about how students talk to and with each other. They are expected to listen to and respect each other and focus on their classmates’ contributions, so that they can understand, challenge, build upon, and refine each other’s ideas. This can lead to facilitative questions (e.g., “does anyone want to add on?”).

These expectations are explicitly imposed on students as a way to promote learning and thinking. To some extent, this approach is similar to dialogically organized instruction (Nystrand et al., 1997), as a variety of dialogue moves, such as revoicing, are key to accountable talk. However, there is more focus on building social norms of classroom talk by enabling students to learn and value accountability in their talk. In other words, it aims not only to enable teachers to become dialogic teachers, but also to enable students to become dialogic learners. In doing so, dialogic norms can be developed by them all, forming a classroom culture.

Research on accountable talk suggests that it leads to “robust, sometimes remarkable, academic achievements for working-class and middle-class students alike, and for students from a range of linguistic backgrounds” (Michaels et al., 2008, p. 286). This research also reveals certain limitations of accountable talk, especially the extent to which its success depends on the commitment and ability of particular teachers. However, this challenge is common to all dialogic education programmes.

Thinking together

Another dialogic approach, Thinking Together, is similar to accountable talk but developed independently in the UK (Dawes et al., 2004). This approach is influenced by Bakhtin’s idea of persuasive voices and Habermas’ notion of an ideal speech situation (1979, 1984), but it is based primarily on Vygotsky’s (1991) theory that the “higher mental functions” originate in forms of social interaction. Thinking Together aims to promote dialogues in the form of “exploratory talk”. This is talk in which “participants pool ideas, opinions and information, and think aloud together to create new meanings, knowledge and understanding” (Mercer et al., 2019b, p. 368).

The Thinking Together approach further proposes that students should engage in “exploratory talk”, allowing differences of opinion to be discussed and explored and leading to the development of an understanding (i.e., ground rules) for everyone engaged in the interaction. This notion of ground rules can be understood as dialogic norms that are co-created and agreed upon by the teacher and students. Such ground rules are applied when students talk and solve problems together. Each class can develop its own set of ground rules, but these are all variations of the ground rules suggested by the original developers of the approach:

- All relevant information is shared openly.
- Each group member should be actively encouraged to contribute to the discussion.
- Everyone should listen to others attentively.
- Each suggestion should be carefully considered.
- Group members are asked to provide reasons for ideas and opinions.
- Constructive challenges to ideas are accepted and a response is expected.
- Alternatives are discussed before a decision is taken.
- The group works together with the purpose of reaching agreement.
- The group, not the individual, takes responsibility for decisions made.

Dawes et al. (2004).

Based on the notion of “exploratory talk” and collaborating closely with teachers, the Thinking Together research team members developed a series of “Talk Lessons” for teaching these ground rules and applying them within the formal primary education (Dawes, 2010; Phillipson and Wegerif, 2017). These lessons encourage teachers to model dialogue and guide children to use discourse as a tool for both individual reasoning and collaborative problem solving. Experimental implementations and evaluations of the Thinking Together approach have been conducted as part of various research projects in countries such as Mexico and South Africa. These studies demonstrate that significant improvements can be achieved in curriculum-specific areas and in scores on Raven’s non-verbal reasoning tests, which is a test that correlates highly with IQ (Mercer and Dawes, 2010; Webb et al., 2016).

Learning communities

The above three approaches focus on promoting thinking among students by enabling them to engage in and expand educational dialogues. Another approach, the learning communities project, reaches beyond the school. As well as promoting educational achievement in the curriculum, this approach is directed toward the social transformation of broader communities based around schools through egalitarian dialogue among all community members, including teachers, students, families, and volunteers. Drawn largely from Freire's ontological stance on dialogues and Habermas's notion of intersubjectivity, [Flecha \(2000\)](#) argues that the implementation of dialogic learning is most influential if it takes place not just in school but in all of a student's important relationship settings, including the home and the workplace. Inspired by similar projects, such as the "Accelerated Schools" project at Stanford ([Levin, 1998](#)) and worker cooperatives and democratic models of work distribution, Flecha intends to develop learning communities capable of analyzing the current situation of their schools and creating a joint vision of the future of those schools.

Specifically, the learning communities project starts with an awareness raising stage, during which issues of social inequality and information literacy are discussed. All participants must engage in this awareness raising; then, they are given the opportunity to decide, jointly, to implement the transformation of the school, forming a learning community. This community is expanded as teaching staff agree to participate, along with the parent association and other stakeholders. A blueprint of action is then drawn up, including actions such as establishing teaching in what are termed "interactive groups". Extra resources are often needed by teachers to handle this new pedagogy. If so, volunteer members of the community are encouraged to come in and help. One example, given by Flecha, is that of a Roma grandmother who herself was not literate but was able to come into school and very effectively organized a learning group. Families are engaged in and offered help with literacy and the use of ICT in the schools. Where conflicts or concerns arise, these are dealt with through dialogues where all parties are equal participants. Through interactive groups and the presence of parents within the classroom, conflicts between groups tend to disappear from the classroom. Evaluations using mixed methods reveal that, according to families in the program, the approach has had a very positive impact on children's achievement and engagement in education ([Flecha and Soler, 2014](#); [Flecha, 2014](#)). The learning community project offers an example of the potential of dialogues to shape and bring into being a shared social vision.

Tensions, dilemmas and future directions

This section explores some of the tensions that exist within dialogic education as well as responding to some of the criticisms that have been leveled at it from the outside. Responses to these tensions and challenges suggest future directions for the development of dialogic education as a strand within the ongoing global dialogue about what we should teach our children and how we should teach it.

Dialogic ideal versus transmission of the curriculum

A true dialogue is open-ended. It is impossible to predict where it will end up. This sets the dialogic ideal in conflict with the idea of a pre-planned curriculum with set learning goals specifying knowledge and skills. It also raises a challenge for assessment. As [Teo \(2019\)](#) points out, the current modes of assessment in many schools still treat "student knowledge and skills as fixed, discrete and assessable through individualized and standardized pen and paper tests" (p. 176).

[Matusov \(2009\)](#) criticizes much so-called "dialogic education" as being essentially instrumental, applying dialogue to serving curriculum goals without ever really becoming truly dialogic. To adopt a genuine "dialogic pedagogy" instead of instrumental dialogic education, teachers should see themselves as the first learners in classrooms, Matusov claims. Highlighting the equal power dynamics, teachers should be ignorant in a sense that they are not afraid to "suspend the certainty of their own knowledge" and to explore it with students again ([Matusov, 2009](#), p. 6). In that sense, both teachers' and students' consciousness should be taken into equal account as they seek information from and with each other ([Skidmore, 2010](#)).

Responding to Matusov's challenge, [Wegerif \(2013\)](#) argues that where there is a curriculum goal this can be approached in a way that also teaches students how to be more dialogic. The goal of promoting more dialogue can be achieved even within a relatively fixed knowledge focused curriculum. In another response to Matusov, [Miyazaki \(in Matusov and Miyazaki, 2014\)](#) points out that every individual has a unique relation with the world that surrounds us, which he refers to as "the ternary relation" (p. 17). That means, when two people interact whether in a monologic or dialogic way, there is always a third relation with the world itself. Miyazaki is perhaps pointing to the significance of the double dialogic referred to by [Linell \(2009\)](#), whereby voices in a dialogue are not just in dialogue with each other but also with their context. As described earlier, [Phillipson and Wegerif \(2017\)](#) turn this double-dialogic idea into a key principle of dialogic education. As well as short term dialogues in classrooms between students and teachers there are also, they claim, long-term dialogues of culture in which conceptual knowledge is developed and transmitted in the form of answers to questions. These long-term dialogues of culture, in science for example, are truly open-ended. While one of the goals of short-term dialogues in classrooms is to develop a capacity for dialogue as an end in itself, another goal is to induct students into

participation in the long-term dialogues of culture. In other words, there are levels of dialogue, and transmitting what has happened in the dialogue so far so that students can join in and take it forward into the future is not the opposite of dialogic education but a key part of dialogic education.

Cultural imperialism

Many approaches (e.g., Thinking Together; accountable talk) involve explicitly promoting a specific form of talk, characterized by largely pre-determined “ground rules” or social norms, which may fail to recognize and value the culture of the students. As Lam-birth (2006, 2009) claims, setting up the ground rules or social norms might be a form of cultural imperialism, in which ways of talking determined among the powerful are imposed on the less powerful. This is also the implication of a critique of the undemocratic way in which teachers sometimes impose ground rules (Barak and Lefstein, 2021). In some cases, the values and norms of the middle classes might be imposed on the working classes. In other contexts, in China for example, it might be argued that western ideas, values, and norms are being imposed upon other cultures.

Littleton and Mercer (2013) respond to this issue with the claim that the exploratory talk promoted in the Thinking Together project is not a class-based or culturally based norm of talking, but a way of talking and thinking together that is educationally effective. In the Thinking Together approach, shared ground rules are developed together by students and teachers on the basis of their experience with group work and their intuitions as to what is likely to be most effective. These ground rules are then meant to be revisited at frequent intervals, at least once a term, to see if they still work or need revising. Agreeing with and building on these points from Littleton, Kershner et al. (2020) argue that what is fundamental are not the specific ground rules but a certain dialogic orientation toward the other. How best to implement this dialogic orientation (in and through exploratory talk) in terms of ground rules will vary depending on the cultural and historical context, but the inter-subjective orientation itself is claimed to be a universal feature of communication that is productive for learning together and has emerged in many times and places.

Dialogic education and Chinese culture

In practice in the USA and the UK dialogic education involves talk in which students initiate dialogues. Fung (2014) points out some tension between dialogic education and Chinese classroom culture which he claims is characterized by “self-effacement” (谦逊, to achieve humility and avoid conflict) and “Li” (ritual, “礼”, to respect others and be less willing to challenge a hierarchy or authority). Teachers, historically seen as a sage or at least as authoritative figures, need to be respected in the Chinese context. As a result, asymmetrical interactions between the teacher and students are likely to be formed and habitually accepted. Additionally, seeking for harmony in Chinese traditional culture may impede argumentative discussions, challenging and competing views (Li and Wegerif, 2014). When contextualizing the Thinking Together program in China, Yang (2016) found that the teacher’s underlying assumptions contradicted some key expectations of dialogue, but she later negotiated the social and cultural aspects of the school with various parties and developed awareness of using talk. The implementation of the program led to the emergence of different ground rules than in the UK, more appropriate for the Chinese classroom context, but, nonetheless, effective for learning (Yang, 2016). As Lefstein (2010) argues, there is no need to remove the existing and inherent tensions of dialogic pedagogy, as new infinite possibilities such as innovative teaching methods are likely to be generated out of the tension of difference and conflict.

Chinese scholars define dialogic education from different perspectives. These definitions can be categorized in terms of Wegerif’s (2019) epistemological level (dialogue for learning) and ontological level (dialogue as learning). Luan and Pan (2010) conclude that educator, learner and learning materials are the dialogic authorities in Chinese classrooms. Li and Wegerif (2014) argue that the Confucian tradition is not against the dialogic but emphasizes cultivating reflection as silent dialogue between multiple voices. Hu et al. (2017) support this, arguing that silence is irreplaceable in Chinese classrooms as it provides time and space for learners to have dialogue with learning materials, ancients, and the universe, and this kind of silent dialogue is essential for students’ understanding of some complex knowledge. A simple hybrid dialogic education practice that has emerged in the Chinese context, for example, is to spend time in silent reflection and individual writing about an issue before engaging in spoken dialogue about it. Liu (2001) describes the potential of dialogic education in the Chinese context and refers to empirical studies conducted by Chinese scholars suggesting that dialogic approaches in Chinese classrooms can have positive effects on students’ learning (Yang, 2016; Hu et al., 2017).

Dialogic teaching and special educational needs and disability (SEND)

International declarations urge countries to ensure an inclusive education to students of all levels (e.g., United Nations, 2006; UNESCO, 1994). However, despite the international declarations, there are barriers to inclusion of those with SEND which include the views of teachers and SEND peers who think that productive dialogue with some SEND students is not possible (Dar-row, 2009). On the other hand, the findings of a literature review carried out by Fernandez-Villardón et al. (2020) suggest that peer support can be used to tackle this barrier. Students without disabilities participating in interventions aimed at improving

SEND students' social skills increased their social support, their requests for repairs in response to unintelligible interventions of their peers with disabilities (Aalsvoort and Gossé, 2007; Weiner, 2005), and their social initiations toward children with SEND. The quality of these exchanges became longer and more reciprocal (Kohler et al., 2007). At the same time, students identified with SEND enhanced their social and communication skills, their reciprocal interactions and their unprompted initiations (e.g., Harper et al., 2008; Kalyva and Avramidis, 2005; Nelson et al., 2007). The number of distractions was also reduced (McCurdy and Cole, 2014).

Learning to use augmentative and alternative communication systems (AAC) may also help to tackle knowledge barriers and facilitate communication with SEND students. AAC is effective in increasing the functional communication skills of students with SEND and it decreases problem behaviors in some individuals with limited or no verbal communication (Hart and Banda, 2010). Students identified with profound intellectual multiple disabilities (PIMD) can also benefit from multimodal communication systems, interactive computed activities and cooperative educational activities. At the same time, their peers without PIMD can also learn these systems to increase reciprocal peer interaction and conduct cooperative tasks with their peers with PIMD (Nijs and Maes, 2014). Computer activities with social interaction can help some SEND students (Lau et al., 2005).

Despite fears that dialogic education will not work with SEND students, it has been found that, given the opportunity and support, people identified with SEND contribute to the dialogues that concern them in their childhood (e.g., Black-Hawkins et al., 2021; Snelgrove, 2005), youth (e.g., Rubio-Jimenez and Kershner, 2020, 2021) and adulthood (e.g., Dew et al., 2019). Despite negative attitudes associated with learners who are perceived as a major challenge for educators (Norwich, 2008), social interactions and communication are always possible and desirable (e.g., Goodwin, 2000; Nijs and Maes, 2014; Teachman et al., 2018).

Technology and dialogic education

Most literature on dialogic education tends to assume dialogue mediated by words in face-to-face or in-person interactions. Others argue that spoken language is just one kind of communications technology that can support dialogue, that it has limitations as well as strengths, and that new forms of dialogic education can be designed for the affordances of different technology (Wegerif and Major, 2019; Trausan-Matu et al., 2021). The use of digital technology has the potential to scale up dialogic education to include a wider range of voices (Wegerif, 2010). A growing body of research has shown the pedagogically enacted affordances of technology can enhance participants' engagement in dialogue, thereby fostering collective knowledge building and collaborative creativity (e.g., Hennessy, 2011; Pifarré, 2020). For example, digital artifacts jointly created by students and teachers on an Interactive Whiteboard open up a shared dialogic space where diverse ideas can be viewed, saved, revisited and modified, not only making different perspectives explicit to participants, but visualizing the evolvement of ideas and externalizing learning trajectories (Mercer et al., 2019a).

More than tools to support dialogue, digital technology has been described as having a voice that can relate to and resonate with other voices in dialogue. Barad's (2007) "new materialist" perspective has been recently brought to the fore and applied to highlight the role of materials, including digital technology, in dialogue (Cook et al., 2019; Hetherington and Wegerif, 2018). The separation of matter and meaning is rejected; instead, "they are always in a relationship of intra-action and inter-connection and affecting each other mutually" (Lenz-Taguchi, 2010, p. 30). This is what Barad (2007) calls "material-discursive". Barad's materialist approach applied to understand classroom dialogues in science when equipment is involved has been described as opening up a "material-dialogic" pedagogy (Hetherington and Wegerif, 2018).

Methodological issues for researching educational dialogues

Published studies on the impact of dialogic education in relation to curriculum learning gains, the development of skills, and the promotion of shared social norms have been positive (Howe et al., 2019; Alexander, 2018; Resnick et al., 2018a,b). Yet, these evaluations tend to use methodologies such as Randomized Control Trials (RCT) which some argue are not really compatible with the philosophical assumptions of dialogism because they seem to assume a monologic view of the world. Much methodology in the social sciences assumes a monologic epistemology, claiming that all apparent differences in perspectives and voices can be reduced to a single correct perspective, a master perspective. Flecha (2000) has responded to this issue by developing what is called a "communicative method" of evaluation that actively engages the voices of participants in the research process. Others argue for adopting mixed methods or design-based research as the methodology for researching educational dialogues, as it is underpinned by a pragmatist epistemology that assumes truths are provisional and are given through both experience and experimenting (Johnson and Onwuegbuzie, 2004, p. 18).

Recently, a new methodology, chiasm, has been developed which aligns better with Bakhtinian dialogism (Kershner et al., 2020). Chiasm suggests that investigating a reality composed of dialogues should combine insider perspectives (emic) with an outsider perspectives (etic) in a systematic way. The insider perspectives could be obtained through the inside-out approach (interviews for example), whereas the outsider perspective could be achieved through the outside-in approach (statistical measures of outcomes for example). The coherence and interlinking of outside-in and inside-out approaches are how the chiasm differs from multi-methods approaches (which can simply juxtapose qualitative and quantitative approaches to answer different

research questions). The chiasm brings outside-in and inside-out approaches together as a whole (answering each research question dialogically, from both the outside in and the inside out), both addressing the research questions with empirical evidence from outside-in and informing them in terms of lived experience from within. This methodology is intended to produce knowledge in the form of a living productive dialogue between inside and outside without reducing either side into the terms of the other.

Summary and conclusions

This chapter offers a brief history of some of the ideas behind dialogic education, outlines some major contemporary approaches to implementing dialogic education, and summarizes research on the impact of dialogic education. Dialogic education means opening up dialogic spaces in which different perspectives can inter-animate and inter-illuminate each other such that learning happens. But dialogic education is more than teaching and learning *through* dialogue; it is also education *for* dialogue, seeking to expand and deepen the dialogic space, enabling students to engage in dialogue more productively, reflectively and collaboratively. As a result of dialogic education, students do not only learn knowledge with deeper conceptual understanding, they also become better at communicating, thinking, and learning together with others. However, there are of course a number of challenges to dialogic education and tensions within dialogic education. We considered just a few of these, focusing on the difficulty of teaching a fixed curriculum through dialogue, the charge of cultural imperialism, especially in the context of China, and the challenge of teaching through dialogue with SEND students. The final two sections on technology and methodology suggest ways in which dialogic education and research on dialogic education might be developing for the future.

The first handbook of research on dialogic education (Mercer et al., 2019b) with over 50 articles from many countries reveals a flourishing global community. Inevitably, given the focus on dialogue, there are many strands to dialogic education and tensions between voices, but there is also the dynamic coherence and optimism of a community moving forward investigating together the meaning and potential of education.

Introduction

Exemplars are cases that represent a more general concept, procedure, or principle. This term is typically used when the case is a special one, either in the sense that it should be followed or copied (e.g., a very well performed procedure to solve a problem) or in the sense that it is a (proto-) typical or representative example. Sometimes exemplars are also special as they show learners that they have to attend to a specific aspect, for example, when solving a probability problem (e.g., order relevant or not).

At times, teachers introduce exemplars as these cases are (also) important in themselves and not (just) because they illustrate something more general. In literature instruction, for example, an outstanding piece by William Shakespeare, by Marcel Proust, by Miguel de Cervantes, or by Johann Wolfgang von Goethe may be read and discussed in schools, within the respective language areas. In history, a specific event might be part of the curriculum as it has heavily influenced the societal development in a country or even a continent (e.g., the French Revolution at the end of the 18th century). It is more typical, however, that cases are presented to enable learners to understand something more general, for example, the *concept* of mimicry in biology (e.g., [Brown and Kane, 1988](#)), the solution *procedure* for certain mechanics problems ([Chi et al., 1989](#)), or a *principle* that is helpful when students try to find a mathematical proof (e.g., [Reiss et al., 2008](#)). Moreover, exemplars can also be employed to show how concepts (e.g., motion or force), solution procedures (e.g., for certain types of mechanics problems), and principles (e.g., Newton's laws) interrelate in a specific domain (here: mechanics).

In this article, it is not possible to cover all the numerous instructionally relevant theoretical perspectives in which exemplars play an important role. We focus on four perspectives (a) that are supported by a substantial body of sound empirical research, (b) that are highly influential, and (c) that focus on student learning; readers interested in teacher education might refer to the literature on analyzing video-based classroom cases for the acquisition of professional vision or, as it has been recently often called, noticing skills (e.g., [Blomberg et al., 2014](#); [Gaudin and Chaliès, 2015](#); [Van Es and Sherin, 2021](#)).

In the next sections, we refer to the following approaches: (a) observational learning; (b) analogical reasoning; (c) example-based learning; (d) problem solving followed by instruction.

Observational learning

This approach is frequently called observational learning ([Bandura, 1971, 1986](#)). However, other labels are used as well: (Cognitive) modeling or social-cognitive theory. In this section, we primarily use the term observational learning. This means that a person learns by observing a model that, for example, solves a problem.

In his seminal book on modeling and observational learning, [Bandura \(1971\)](#) stated: "This volume is principally concerned with learning by example" (p. 1). He made the strong assumption that most behavior is learned by observing other people, that is, from example cases. Learning takes place if the learners pay attention to relevant behavior (*attention*), if they encode and remember the model activity (*retention*), and if they are capable of reproducing this type of behavior (*reproduction*); furthermore, the learners have to be motivated to reproduce the behavior (*motivation*) (e.g., [Bandura, 1986](#)).

Especially in academic learning, *abstract modeling* is relevant. This term means that a model demonstrates a behavior that follows an abstract rule or principle (e.g., of how to formulate well-substantiated arguments), in contrast to behavior that can be directly mimicked (e.g., how to make a specific knot in a rope). In the case of abstract modeling, the learners construct rules that can guide their future behavior ([Bandura, 1986](#)).

Fig. 1 A model showing how to solve a physics problem. Used by Hoogerheide et al. (2016), as shown in Van Gog et al. (2019).

In recent years, models in the internet (e.g., presented by YouTube or Khan Academy) have become an important source of learning. Fig. 1 shows a model that demonstrates how to solve an electrical circuits troubleshooting problem (Hoogerheide et al., 2016). The learners should learn abstract rules or principles to become able to solve similar new problems. Hence, this is a case of abstract modeling.

Bandura (1986) suggested providing multiple models (examples) to learners. Multiple examples make it not only easier to abstract the general rule or principle behind the models' behaviors; multiple models provide also a better chance for the learners to identify with at least one model and to learn effectively from it (e.g., Schunk et al., 1987).

Most research on observational learning in educational contexts did not try to prove the effectiveness of observational learning by comparing it to other forms of learning. Note that Bandura made the fundamental assumption that most behavior is learned by observing others. Instead, most studies analyzed the effects of different variants of observational learning, for example, learning from a smoothly performing mastery model or a coping model showing how to overcome impasses (e.g., Schunk and Hanson, 1985), learning by abstract modeling with(out) support to induce the underlying principles (e.g., Decker, 1980, 1984; Rummel et al., 2009), or learning from a model (dis-)similar to the observer (e.g., in terms of gender, age, or perceived competence; e.g., Braaksma et al., 2002); a similar model can lead to a higher self-efficacy of the learner and thereby better learning (e.g., Schunk et al., 1987).

Nevertheless, some research also tested the relative effectiveness of abstract modeling in comparison to other forms of learning. For example, it was found to be superior to foster students with problems in mathematics by cognitive modeling than by didactic instruction (e.g., Schunk, 1981); observational learning enhanced college students' writing skills more than working on practice problems (e.g., Zimmerman and Kitsantas, 2002); observing video models on productive cooperation was more effective for learning how to cooperate than learning by "scripted" doing (e.g., Rummel et al., 2009).

For developing self-regulation in academic domains such as writing, Schunk and Zimmerman (1997, 2007) have proposed a four-stage model with observational, emulative, self-controlled, and self-regulated stages. Over the development through these stages, regulation proceeds from social sources (observational, emulative) to self-regulation (self-controlled, self-regulated). At the observational stage, a learner profits from observing models that explain and demonstrate the execution of a skill, thereby learning the main features of a skill cognitively, that is, without necessarily performing the skill itself. At the emulative stage, a skill must be executed for further learning. The learner's skill execution approximates the model's performance. However, the learners do not fully copy the model but emulate the model's general pattern. As the learners need model cases for learning in the first two stages, these stages are considered as primarily social. At the self-controlled stage, the learner executes a skill independently when working on a problem, with a mental representation of the skill in mind. However, the skill is still structured after models. Learners have yet to develop a mental representation independent from the models. At the final self-regulated phase, learners are increasingly able to adapt a skill to changes in the problem-solving context. Note that the provision of example cases is pivotal in the first two stages (observational and emulative) to initiate skill acquisition. On this basis, self-regulated skill execution can developed in later stages.

Besides this social-cognitive model, there are also other instructionally relevant models that were influenced by the perspective of observational learning. For example, the well-known Self-Regulated Strategy Development (SRSD) approach by Harris and colleagues (e.g., Graham and Harris, 2018) was designed to foster students' writing strategies and skills; meanwhile SRSD has also been successfully applied in other subject areas such as mathematics or science (see McKeown et al., 2021). This instructional framework includes six stages, the third stage being "Model it." Interestingly, Dignath et al. (2008) found, in their meta-analysis of self-regulation training programs for primary school students, that interventions with a theoretical background in Bandura's perspective provide overall the best training effects (as compared to training interventions having their theoretical foundation in metacognitive or motivational theories).

In recent research, the concept of observational learning is also used to design and analyze forms of technology-enhanced learning. For example, a number of studies investigate how videos presenting models for academic learning (often called video modeling examples) could be optimized (Fig. 1). For example, research suggests that it is helpful when a model behavior is shown from a first-person perspective (i.e., video shows what the model sees) rather than a third-person perspective (i.e., video shows the model from an observer's point of view; Fiorella et al., 2017).¹ For other ways to improve such video models, the reader might refer to Mayer et al. (2020).

Another application in technology-enhanced learning is "Eye Movement Modeling Examples" (EMME), which show the eye-movements of an expert or a successful learner when working on a problem or when studying learning materials. For example, EMME can show the eye movements of an instructed model demonstrating effective processing strategies for multimedia learning materials with text and pictures. Such models can actually foster later learning from multimedia materials (e.g., Krebs et al., 2019; Mason et al., 2015).

In summary, a basic assumption of this perspective is that most behavior is learned from a specific form of exemplars, that is, models showing how to perform a task or solve a problem. Observational learning from models can also be successfully exploited in educational contexts, in which this form of learning is typically used for teaching strategies.

Analogical reasoning

Seminal research in this area was published in the 1980s as basic research on human reasoning (e.g., Gentner, 1983; Gick and Holyoak, 1980, 1983). In particular, it analyzed to what extent knowledge of exemplar cases can be exploited to solve analogous problems. Problems are analogous if they have the same structure with respect to their solution though the surface features (e.g., numbers, objects, or persons) may differ. For example, mathematical word problems are analogous when they can be solved by applying the same mathematical principle (e.g., addition rule in probability), even if the numbers, objects, or persons differ in the problem formulation. Another example is the Doppler effect which is usually known by laypersons as a shift in a siren's sound (i.e., a shift in wavelength) when an emergency vehicle is approaching us and then recedes again. By analogy, laypersons can also understand that similar changes in the wavelength of a star's light occur when it is approaching us or receding from the earth. More formally expressed, the superficial features such as numbers, objects, etc. can differ in analogous cases but the relations between these entities are the same (Gentner, 1983). To take up the two Doppler examples, they differ as to whether they refer to cars or stars or whether there are light waves or sound waves. However, the relation between the motion of the wave source (i.e., car or star) and the change in the wavelength corresponds in both cases. Cars and stars play the same role and light waves and sound waves play the same role; structurally, however, cars and stars as well as sound waves and light waves are exchangeable.

The process of analogical reasoning (and resulting learning) can be described by four stages (see Holyoak, 2012). Following is an explanation of what happens in the case of successful analogical reasoning. In stage 1, a student encounters a first example or, in some cases, also more analogous examples (e.g., probability word problem(s) to be solved by applying the addition rule).² This or these case(s) form the knowledge source for later solving analogous problems; for these reasons, the cases are often called *source* in this research area. In stage 2, a student encounters a new case (e.g., word problem to be solved by the addition rule), which is often called *target*. Memory traces of potentially relevant source cases are activated (e.g., word problems to be solved by the addition rule but maybe also word problems to be solved by the multiplication rule), and relevant cases (i.e., "addition rule cases") are selected. In stage 3, the new case (target) is mapped onto an analogous source case or even to several source cases. To take up again the Doppler examples, a student notices that, in the new case, the star plays the role of the car (mapping the star onto the car) and the light waves play the role of sound waves (mapping the light waves onto the sound waves). Most importantly, however, the identical relation between the wave source's motion and the shift in the wavelength is mapped one onto the other. In stage 4, mapping two or more examples to each other leads to the construction of a schema that represents relations and abstract role slots. In the ideal case, these abstract slots can be flexibly filled in by the superficial features of further new cases (e.g., Doppler echocardiogram in the medical domain).

Note that successful analogical reasoning leads not only to the solution of problems but also to substantial learning as schemata are constructed that can be applied to new cases. In addition, it was found that learners store both in their memory, the schema and the cases (Reeves and Weisberg, 1994; Ross, 1987, 1989.). Even if a schema has been constructed, the cases may play an important role in further problem solving and learning. It requires substantial expertise to "see" instantly that a schema applies when encountering a new case. A possibility for less expert learners is that a new case reminds them of an analogous case (e.g., Ross, 1987, 1989), and if the old case is mentally connected to an abstract schema, this schema can be applied to the new case. In a nutshell, example cases have several functions. They help to solve new problem cases, to construct abstract schemata, and they help to access these schemata by "reminders" (Ross, 1987, p. 629).

¹Of course, this can only hold true when the model's motoric behavior does not play an important role; often, such behavior cannot (fully) be seen from a first-person perspective.

²In basic analogical reasoning research as well as in educationally-oriented research, the rule or principle underlying the case solutions is sometimes already provided in stage 1. For the sake of simplicity, we do not consider this option here. This omission seems to be justified as it is the less typical option, and educationally it does not seem to be a preferable option (Alfieri et al., 2013).

Note, however, that the preceding description focused on successful cases of analogical reasoning. Yet, many students might not be able or willing to perform the required cognitive processes. Typical problems are as follows (see, e.g., [Gray and Holyoak, 2021](#); [Vendetti et al., 2015](#)): Students might have poor knowledge of the potential source cases (e.g., incomplete representations; stage 1). Another major problem is that many students do not spontaneously (i.e., without a hint) refer to a relevant source case (stage 2). Students might have also difficulties in mapping the source and target cases because they are “seduced” to map only superficial features (e.g., there may be children in two probability word problems but they play a different role so that they should not be mapped onto each other; stage 3). Students may also fail to infer the abstract structure behind analogous cases so that no (adequate) schema is constructed (stage 4). Overall, unsupported analogical reasoning is a demanding process imposing high cognitive load on the learners so that in particular learners with low prior knowledge frequently fail ([Gray and Holyoak, 2021](#)).

Against the background of these deficits, some reviews have provided guidelines on how to support students to make this learning method effective ([Alfieri et al., 2013](#); [Gray and Holyoak, 2021](#); [Vendetti et al., 2015](#)): For example, teachers may ensure that the students have a basic understanding of the source by explaining the source case and, thereby, highlighting its relevant features (stage 1). To help students select the right source(s) when trying to solve a new case, teachers might provide a hint to the source(s) or a source case and a case target can be presented side-by-side so that the source is visible when comparing the cases (stage 2). When students need to map cases, in particular with respect to structural correspondences, teacher can direct students’ attention to relations instead of to objects, persons, or numbers while comparing (stage 3). Finally, students are supported to form an abstract schema, if teachers provide explicitly the relational structure (i.e., principle) after comparing the examples (stage 4).

Overall, well-implemented learning from analogous cases is an effective method, as shown by the meta-analysis by [Alfieri et al. \(2013\)](#). This effectiveness was not only determined in controlled lab studies. For example, [Richland et al. \(2007\)](#) also found that US mathematics teachers used relational comparisons relatively often but they provided little help to their students such as keeping the source visible to learners during the comparison with the target or using gestures signaling important mappings. Hong Kong and Japanese teachers provided more support, which might explain some of the achievement differences between these countries in favor of the Asian region. The latter assumption is backed up by [Richland and McDonough \(2010\)](#) who found, in their classroom experiments, that providing visibly aligned source and target problems during initial learning, as well as using gestures to facilitate mappings, led to favorable learning outcomes.

In summary, this perspective emphasizes the role of exemplars stored in memory in three respects. First, stored source cases can help to solve new (target) problems; second, multiple cases form the basis for the induction of abstract schemata for later problem solving; third, when encountering a new problem, learners might be reminded of a previous case that helps accessing the relevant abstract problem solving schema. However, many learners need support in order to engage in successful analogical reasoning.

Learning from worked examples

Worked examples consist of a problem or task (e.g., forming a good counterargument to a claim) and its solution (e.g., a properly structured counter-argument). Worked examples with mathematical solution procedures usually also provide the solution steps leading to the final solution (e.g., mathematical word problem, equation(s), and the final solution). In some cases (see [Fig. 2](#)), worked examples are also “enriched” by elements designed to help learning, for example, explanations or color codes helping the students understand correspondences between a figure and an equation.

Seminal research on learning from worked examples (frequently also called example-based learning) was conducted in the 1980s by [Sweller and Cooper \(1985\)](#), as well as [Cooper and Sweller \(1987\)](#). They compared learning by solving problems with learning by studying worked examples. For example, students (9th grade) learned to solve algebraic equations ([Sweller and Cooper, 1985](#), Exp. 3). First, all students studied worked examples within the introduction to this topic. Following this, the students in the conventional problem-solving condition tried to solve eight problems covering four types of problems. The students in the worked-example condition encountered the same eight problems, but the solution steps of the first problem of each pair of structurally identical problems was shown (i.e., example-problem pairs). Students in the worked example condition, as compared to the conventional condition, made fewer errors in a final posttest with structurally identical problems and they needed less time for the acquisition phase well as for the posttest. [Cooper and Sweller \(1987\)](#) could also find positive effects of studying worked examples on the performance on later transfer (i.e., not structurally identical) problems. This advantage of studying worked examples—which was also found in many subsequent studies—is usually described as “worked example effect” (e.g., [Renkl, 2014](#); [Sweller et al., 2019](#); [Van Gog et al., 2019](#)).

To prevent a common misunderstanding, the use of one worked example between introducing a principle (e.g., addition rule in probability) and solving corresponding problems is not considered as example-based learning. Such a sequence was actually used in the conventional conditions (i.e., control conditions) in the seminal studies by [Sweller and Cooper \(1985\)](#), as well as [Cooper and Sweller \(1987\)](#). Example-based learning means that students study multiple examples before problem solving, either in the form of several example-problem pairs (as in [Sweller and Cooper, 1985](#)) or a sequence of examples only (see also [Van Harsel et al., 2019](#)).

The advantage of worked examples can be explained as follows ([Renkl, 2014](#)). If students have just started to learn, for example, about certain laws in physics (principles), they have developed just a rudimentary understanding of these laws. Hence, these students cannot rely on a real understanding of these laws when they work on corresponding problems. As consequence, the students frequently engage in superficial strategies to, nonetheless, find a solution (e.g., copying the solution of

Fig. 2 A worked example from probability, with color coding and to be supplemented explanations. Taken from Berthold and Renkl (2009).

a former problem and adapting the numbers). Such superficial strategies, in many cases, may lead to the correct numerical solution but they barely foster the understanding of the physics laws and of how to apply them for solving problems. Thus, solving problems by relying on superficial strategies can be viewed as extraneous (not productive) cognitive load (Sweller et al., 2019). Hence, learners should first study worked examples to reach an understanding of underlying principles (e.g., physics laws, mathematical theorems) before they engage in solving problems. With a sufficient understanding of the principles, problems can then be solved in a principle-based way, which deepens understanding and may eventually also lead to automation (Renkl, 2014). Against this background, learning from worked examples is helpful for the initial acquisition of cognitive skills (e.g., learning to solve a certain type of physics problems) when the main goal is to gain an understanding of principles and their application. In later stages of skill acquisition, when the goals are fine-tuning a skill and, in part, to automate it, problem solving is superior (e.g., Kalyuga et al., 2001; Renkl, 2014).

Initially, the worked example effect was primarily shown in mathematics and in domains with mathematical solution procedures (e.g., in physics). Such learning domains are usually classified as well-structured. However, the worked example effect has also been found in many ill-structured domains where just heuristics ("rules of thumb") apply, instead of algorithmic solutions. Examples of such ill-structured domains in which worked examples effectively fostered learning are finding mathematical proofs (Reiss et al., 2008), cooperating effectively (Rummel et al., 2009), identifying styles of designers (Rourke and Sweller, 2009), effective concept mapping (Hilbert and Renkl, 2009), analyzing legal cases (Nievelstein et al., 2013), arguing properly (Hefter et al., 2014), and writing essays in English literature (Kyun et al., 2013); many more examples could be provided.

As it is the case with other learning methods (Pant, 2014; Renkl, 2015), learning from worked examples is not always helpful. Three important boundary conditions are as follows. First, as already mentioned when providing the theoretical explanation of the worked example effect, worked examples are for initial skill acquisition. Providing such examples to learners with good prior knowledge of the learning content is redundant and provides no advantage or even leads to less learning than solving problems (e.g., Kalyuga et al., 2001). Second, many learners study worked examples just superficially, for example, without referring to the underlying principle, which can lead to little learning (e.g., Hilbert and Renkl, 2009; Renkl, 1997). Third, studying worked examples induces less extraneous load than solving problems, which is a major reason for the worked example effect (see the theoretical explanation for the worked example effect). However, when extraneous load is increased by having worked examples with multiple representations (e.g., diagram and equation) that are difficult to map one to the other, the worked example effect disappears (e.g., Tarmizi and Sweller, 1988).

Appropriate instructional design can help to counteract these problems. First, to avoid the effect of redundant examples, the solution steps of the examples can be gradually faded out with increasing learner knowledge. After the initial study of fully worked examples, learners have to determine single solution steps and later they solve the whole problem on their own. Fading provides the learners with a smooth transition from studying worked steps to problem solving (Renkl and Atkinson, 2003). As the learners differ in their speed of acquiring knowledge, it is best to fade worked steps adaptively according to the individual increase in understanding, which can be accomplished by technology-enhanced learning environments (e.g., Salden et al., 2010). Second, to counteract superficial processing, the learners can be prompted to explain to themselves what principle(s) (e.g., physic laws) underlie an example's solution. Self-explaining fosters learning outcomes (self-explanation effect; e.g., Chi et al., 1989; Renkl and Eitel, 2019; Rittle-Johnson et al., 2017). Sometimes in example-based learning, several examples are presented simultaneously, and self-explanation prompts require the learners to compare these examples and their solution procedures (e.g., Schalk et al., 2020). Such an instructional procedure could also be regarded as an analogical-reasoning learning procedure; in this case, the boundaries between the two approaches becomes blurred. Third, to reduce extraneous load, the mapping between different representations can be eased for the learners (e.g., Renkl, 2022), for example, by color coding (i.e., using the same color for elements corresponding across different representation; Berthold and Renkl, 2009, Fig. 2) or by an integrated format (e.g., writing the equations parts to corresponding locations in the diagram; Tarmizi and Sweller, 1988). In the case of video-based worked examples, the presented information often quickly disappears and is replaced by other new information (transient information effect; Singh et al., 2012). Learners profit if the video stops after smaller meaningful event units (segmenting; Spanjers et al., 2011, 2012). For further instructional designs to optimize example-based learning, the reader might refer to Renkl (2014, 2017, 2022).

In summary, it is a very robust finding that learning from worked examples is an effective option to foster the initial acquisition of cognitive skills, when the main goal is to gain an understanding of principles and their application. This is true not only in domains with mathematical solutions but also in domains where just heuristics apply. However, to fully exploit the potential of example-based learning, appropriate instructional design has to be used.

Problem solving followed by instruction

The approach of problem solving followed by instruction—which means in this case direct forms of instruction with explanations of the to-be-learned contents—is typically abbreviated as PS-I (e.g., Loibl et al., 2017). Corresponding research usually tries to show that (under certain circumstances) PS-I is superior to the more traditional sequence of direct instruction followed by a phase of problem solving, in which students apply what has been explained before (I-PS). It is argued that it is too difficult for (many) students to get to an understanding of the principle(s) to be learned when beginning with direct instruction. The problem solving phase should prepare the students to profit optimally from the following direct instruction so that they can understand the principle(s) (e.g., Kapur, 2015). At first glance, this approach does not emphasize the role of exemplars during learning. However, when looking at how the two typical PS-I models, “productive failure” (e.g., Kapur, 2008, 2015) and “inventing” (e.g., Schwartz et al., 2011), arrange the PS phase, it is clear that specifically designed sets of example cases play a crucial role.

In productive failure (e.g., Kapur, 2008, 2015), students get a problem related to a to-be-learned concept (e.g., variance/standard deviation) that they cannot solve. For example, students (here: in triads) worked on the following problem without support or guidance (Kapur, 2012, 2015): A committee has to decide which one of three soccer strikers should be awarded with the prize for consistent performance. The students (9th grade) get a table with the number of the strikers' goals in the years from 1992 to 2011: Mike Arwen: 14, 9, 14, 10, 15, 11, 15, 11, 16, 12, 16, 12, 17, 13, 17, 13, 18, 14, 19, 14; Dave Backhand: 13, 9, 16, 14, 10, 11, 13, 14, 15, 19, 14, 12, 15, 14, 17, 13, 14, 18, 14, 15; Ivan Right: 13, 18, 15, 10, 16, 10, 17, 10, 12, 14, 19, 14, 18, 9, 10, 18, 11, 10, 18, 18. The committee wants to decide on the basis of a mathematical index for consistency. The specific instructions students received were as follows: “(1) Design as many different measures of consistency as you can. (2) Your measure of consistency should make use of all data points in the table. (3) Show all working and calculations on the papers provided” (Kapur, 2015, Appendix A). In the following phase, the teacher compared the different student-generated solutions and then introduced the canonical solution; the students could, thus, compare their wrong or suboptimal solutions to the canonical solution. Finally, the students worked on three practice problems, and the solutions were discussed in the class.

Note that the set of three cases was specifically designed (e.g., all three strikers had the same range and mean) and played a substantial role in the first PS phase. The cases had to be compared, like in analogical reasoning arrangements. Different from analogical reasoning, however, there is no general principle that is intrinsic to the (set of) cases (e.g., in other contexts, the cases could also be compared with respect to the average number of goals per season), and the students are not expected to infer a principle correctly. The prime intended function of this problem solving phase is that the students activate and differentiate their prior knowledge in relation to the target concept (here: variance/standard deviation).

The approach of inventing (e.g., Schwartz et al., 2011; Schwartz and Martin, 2004) is very similar. However, Loibl et al. (2017) identified two important differences. First, in inventing, the teacher might not take up the previous student solutions before providing instruction about the canonical solution (as it is common in productive failure). Second, “contrasting cases” are used. This means that there is a set of simpler cases, as compared to productive failure, and the cases are very similar to each other; they ideally differ just in one structurally relevant aspect. Thereby, the students' attention should be guided to this aspect. Loibl et al. (2017) illustrated how the already provided materials of Kapur (2012, 2015) might look in an invention study: “Contrasting cases #1: ● Player A: 9, 10, 10, 11 ● Player B: 5, 10, 10, 15/Contrasting cases #2: ● Player B: 5, 10, 10, 15 ● Player C: 5, 5, 15, 15” (p. 701; see also Loibl et al., 2020). Note

that this different design of the example sets makes also a difference with respect to whether the students can determine on their own to what extent their inventions work. By their simple and overlapping design, it is very easy to see that player A is more consistent than player B, and player B is more consistent than player C. Hence, it is not hard for the students to check whether their invented indices discern the cases in the appropriate way; they are less dependent on external feedback in this respect.

Loibl et al. (2017) concluded in their review that PS-I, as compared to I-PS, does not reliably foster the performance on problems analogous to the ones encountered during learning. However, there are positive effects on conceptual understanding and on transfer if the instructional procedure includes contrasting cases and/or taking up the students' solution in the instructional phase. If both are missing, no positive effects can be expected. In addition, their analyses suggest that the following set of mechanisms is responsible for the positive effects of an initial problem solving phase: (a) The students activate their prior knowledge; (b) they become aware of their knowledge gaps; (c) the students' attention is directed to structural features related to the underlying principle, which can, in particular, happen when working on contrasting cases or when student solutions are compared to the canonical solutions. This is why contrasting cases and/or taking up the students' solution in the instructional phase is important. In addition, the findings of Glogger-Frey et al. (2017) suggest that experience in inventing activities helps to make these activities productive. Note that the effects of PS-I do not seem to depend on students' success in the problem-solving phase; even failure prepares for further learning (e.g., Loibl and Rummel, 2014).

Loibl et al. (2017) as well as the discussion in the preceding paragraph focused on cognitive mechanisms. However, motivational mechanisms may also account for the positive effects of initial problem solving. Such an activity can lead to more epistemic curiosity about and situational interest in the learning content (e.g., Glogger-Frey et al., 2015). To date, however, there is no clear picture on the interplay between cognitive and motivational factors in PS-I learning.

In summary, PS-I requires the students to inspect specifically designed sets of example cases and to invent an index for comparing these cases. These invented indices, which are, in most cases, (partly) incorrect, are then related to the target concept (i.e., the correct index). Even without finding the correct index on their own (i.e., "failure"), students can profit from such problem solving activities as they prepare them to learn from subsequent direct instruction.

Relations between theoretical perspectives

There are cases in which different strands of research investigate very similar phenomena but hardly take notice of each other. Fortunately, this is not true in the case of the four perspectives just described. In many studies, researchers refer to more than one of these perspectives. This multiple referencing is usually not done to test competing hypotheses from the different perspectives; instead they are primarily exploited as complementary perspectives. It is beyond the scope of this article to review the findings of research relying on such multiple perspectives, but a "flavor" of such research should be provided by the following.

The research area that is most readily connected to the other areas is example-based learning. To illustrate these interconnections, we refer to selected studies. There are studies using worked examples in form of videos that show persons demonstrating how, for example, a mathematical problem is solved (e.g., on YouTube). Such worked examples directly call for taking factors into account that are usually considered in observational learning such as model-observer similarity or the models' perceived expertise (e.g., Hoojerheide et al., 2016, 2018). In other studies, there are several related principles that should be taught by example-based learning (probability problems with and without replacement; e.g., Berthold and Renkl, 2009). Then, sets of examples are typically provided that also help differentiate the different related problem types (e.g., with and without replacement). For this purpose, students are required to compare example cases. In such circumstances, it is sensible to also refer to analogical reasoning research for tried-and-tested support measures to support example comparison and, thereby, to optimize learning (e.g., presenting examples side-by-side; Schalk et al., 2020). Finally, there are studies testing whether not only the typical example-based arrangements (i.e., example-problem pairs or examples-only) lead to effective learning but also problem-example pairs, which share some similarities with the PS-I approach (e.g., Van Harsel et al., 2019).

Studies connecting the other perspectives are not so numerous but they can also be found. For example, Jacobson et al. (2020) combined ideas from productive failure and analogical reasoning to foster across-domain transfer with respect to applying complex systems principles. Hartmann et al. (2020) found that PS-I can be effective not only when learners "fail" themselves but also when they observe a model with failed problem-solving attempts prior to instruction. Finally, Wu and Weng (2013) found that models displaying analogical reasoning can help teach architecture design.

In summary, the four perspectives on exemplars discussed in this article can be seen as complementary. Against this background, largely shared instructional implications can be derived from this set of perspectives.

Instructional implications

It is beyond the scope of this article to discuss instructional design issues for learning from exemplars in detail (for this purpose see, e.g., Loibl et al., 2017; Gray and Holyoak, 2021; Renkl, 2014, 2022; Schunk and Zimmerman, 1997; Sinha and Kapur, 2021; Van Gog et al., 2019; Vendetti et al., 2015). However, we present selected instructional guidelines that relate to the theoretical perspectives discussed in this article. They refer to the use of the multiple examples, to how sets of examples might be composed (inter-example features), to how single examples should be designed (intra-example features; Atkinson et al., 2000), and to how the

learner's processing of the examples can be fostered. To facilitate the mapping between the previously discussed perspectives and the following practice recommendations, the following abbreviations will be used: OL (observational learning), AR (analogical reasoning), WE (worked examples), and PF-I (problem-solving before instruction).

Multiple examples

An obvious common recommendation of the four approaches is to use multiple example cases. In part the assumed advantages of multiple examples differ. However, this does not mean that the specific advantages emphasized in one perspective do not also apply to learning arrangements designed (primarily) from another perspective. More specific recommendations with respect to how to structure sets of multiple examples are provided in the subsequent sub-sections.

Inter-example features

Recommendable features of example sets (i.e., inter-example features) depend on the specific learning goal and the specific learning setting:

- (a) If there is a principle and its application that should be understood, it is recommendable to provide a set of analogous example cases (WE, AR). Two variants have to be differentiated in this context: the principle is or is not presented up-front. If the principle is presented up-front (typical of WE), subsequently studying multiple analogous examples (or example-problem pairs) can foster the learners' understanding of the principle and its application. Thereby, the learners get well prepared for learning by solving further related problems in a principle-oriented way. If the principle is not presented up-front (as typical of AR and obligatory in PS-I), the learners get the opportunity to (try to) infer the principle by "seeing" through the superficial features on the relational structure (i.e., principle; AR). In the case of productive failure arrangements, it is not expected that the learners will correctly induce the "full" principle but they are prepared for learning the principle by being sensitized for structural features (PS-I).
- (b) If the goal is to discern easily mixed-up problem categories (e.g., rule of three in mathematics for direct proportions or for inverse proportions), the learner should work on a set of examples that provide the opportunity to compare cases for the different categories (e.g., providing them side-by-side); thereby students learn to discern problems related to the different categories (WE).
- (c) If models are the cases to learn from (OL, WE), multiple examples have the advantage that different learners can find at least one model to identify with, which is a favorable condition for learning (OL).

Intra-example features

All perspectives emphasize that the learners' attention should be directed to structural aspects related to the underlying principles. Unnecessary processing demands and resulting extraneous working memory load, which can also lead to cognitive overload, should be avoided (WE, AR). Two important possibilities to avoid extraneous load are as follows.

- (a) As already mentioned in the section of example-based learning, it is essential in the case of worked examples with multiple representations (e.g., text, graphic, or equations) to ease mapping between these presentations, for example, by color coding or integrated format (e.g., Renkl, 2022; see Fig. 1). It is very likely that this finding generalizes also to the other types of learning arrangements (OL, AR, PS-I), as research on multimedia learning strongly suggests (see, e.g., Mayer, 2021).
- (b) In the case of video-based worked examples, models, or source analogs, which can be often found on the internet, the transience of information is a challenge for students that should not be underestimated (e.g., Singh et al., 2012). If the learners are briefly inattentive they might miss important information. Such inattentiveness can be due to mind wandering (e.g., Risko et al., 2012, 2013) or attention to salient, but not important information in the video (e.g., a case of unusual wording in the explanatory narration or the accent of a model). It might also be that a learner thinks a bit longer about an important to-be-learned aspect so that new information is missed. To mitigate this problem, segmenting can be used, that is, the videos stop after each meaningful event unit (e.g., Spanjers et al., 2011).

Learners' example processing

A well-known problem is that many learners do not spontaneously engage in self-explaining models or worked examples (OL, WE) or in comparing example cases (AR, PS-I). There are several possibilities to address such problems.

A tried-and-tested option is to use prompts that ask the learners to explain to the themselves the principles underlying a model (OL) or a worked example (WE). Prompts can also be used to enhance learners' processes of example comparison (AR, WE). Note, however, that such support may not have an added value in the case of PS-I where it is not crucial that the comparison processes lead to the induction a principle (see Loibl and Rummel, 2014). In this case, it seems more important that the student solutions and the canonical solution are compared in an instructional phase.

Another tried-and-tested option in the case of worked examples or examples to be compared is to use short training interventions (AR, WE). Such an intervention to foster the processing of worked examples was, for example, developed and tested by Renkl et al. (1998). This intervention (10–15 min) included the following components: (a) information on the importance of self-explanations, (b) modeling self-explanations with one worked example (here: from interest calculation), and (c) coached practice with another example (for a similar training intervention see Hodds et al., 2014). Gentner et al. (2003) has developed a successful short training intervention for learning by example comparison (AR).

Another option leading to enhanced learning is imagery. For example, an observed model behavior can be mentally repeated (e.g., Eaves et al., 2016). Similarly, it fosters learning when the students close the eyes after having studied a worked example and then imagine the solution procedure (e.g., Ginns et al., 2003).

Outlook

Overall, it is fair to say that the topic of this article is relatively well-researched. This is at least true with respect to the functions of exemplars for learning, to the learning processes, to the effects of corresponding learning arrangements, and to instructional design options for optimizing learning. Nevertheless, there are important issues for future research.

Although the cognitive aspects are well researched, there is relatively little research on motivational processes and factors as well as their interplay with cognitive factors. This is especially true for research on example-based learning, analogical reasoning, and PS-I. In observational learning, at least the motivational concept of self-efficacy has received substantial attention (e.g., Braaksma et al., 2018; Schunk, 1981; Schunk and Hanson, 1985). Future research on motivational issues and on the interplay of motivation and cognition could provide very helpful information for implementing effective forms of learning from exemplars in classrooms.

Up to date, there are some studies, in which forms of learning from exemplars were implemented in classrooms (e.g., Reiss et al., 2008). However, such studies are rare. This is more than pity, as there is an ample research base (at least on cognitive issues) that allowed for promising implementations. Whether the last statement is just a “pious wish” of a researcher in this area—the author of this article—or an “accurate expert judgment” should be investigated in future implementations and design-based studies.

Introduction

In order to improve, individuals need to generate, receive and act upon feedback of different forms. It is necessary to appreciate what has been done well, become more aware of weaknesses and develop action plans for ongoing improvement. Indeed, it is well-recognized that feedback is one of the most significant levers to enhance student achievement (Hattie and Timperley, 2007), yet at the same time feedback processes are complex, and often fail to produce a worthwhile return on the time and resources invested (Carless and Boud, 2018).

In higher education, there is a wide range of evidence that undergraduate students do not appear to be particularly satisfied with how feedback processes are generally managed (e.g., Buckley, 2020). National quality assurance surveys in the UK, Australia and elsewhere consistently suggest that feedback is one of the least satisfying aspects of the student experience. Admittedly, it is not clear how students are defining feedback in these kinds of surveys, and they may also be conflating it with assessment grades which often provoke emotional reactions.

This sense of dissatisfaction about feedback processes is reinforced by evidence that students do not find the feedback they receive from their teachers easily understandable, useful or actionable (Winstone et al., 2017). Teachers' frustrations with grading and marking are also apparent in that they often experience these types of work as being time-consuming and relatively unproductive, not least because of feedback doing double duty involving grade justification, commentary and quality assurance demands (Winstone and Carless, 2021). A related challenge is that students and teachers seem to have different views of what feedback is and what it should do (Adcroft, 2011; Carless, 2006). First-year undergraduates are influenced by the close relationships and guidance that they experienced in high school. This might reinforce naïve perceptions that feedback means being told what to do in order to obtain good grades. When students think of feedback in terms of telling and guiding, they are sometimes under-prepared for the autonomous learning culture of higher education. Teachers often envisage a more active student role in feedback processes than some learners are prepared to adopt (Adcroft, 2011).

A consequence is that how feedback is conceptualized and defined is both critical and disputed. A useful conventional view is to see feedback as mainly comprising information provided by an agent (e.g., teacher, peer or self) about aspects of performance or understanding (Hattie and Timperley, 2007). This view of feedback is roughly similar to dictionary definitions of feedback: "If you get feedback on your work or progress, someone tells you how well or badly you are doing, and how you could improve" (Collins COBUILD, 2018). Conceptualizing feedback as an information-sharing process has been referred to as the "old paradigm" of feedback (Winstone and Carless, 2019) in that it underplays recent developments in emphasizing the learner role in generating, making sense of, and using feedback of different forms. Accordingly, a more process-oriented social constructivist view emphasizes the student role in using feedback for enhancement purposes (e.g., Carless and Boud, 2018). This way of thinking has been referred to as a "new paradigm" of feedback (Winstone and Carless, 2019) placing the learner firmly at the center of feedback processes through strategies, such as peer feedback and self-assessment. New paradigm feedback practices are defined as approaches which emphasize students generating and acting upon feedback inputs of different forms.

Internal feedback is an important concept congruent with new paradigm feedback processes. Internal feedback denotes the insights that students generate when they compare their current knowledge and competence against some reference information, such as the work of their peers (Nicol, 2021). For Nicol, external information received by learners needs to be transformed into internal feedback if it is to influence ongoing development. Building on these strands of thinking, feedback is defined in this chapter as interactive processes through which learners generate performance-relevant information to enhance their work or learning strategies. Performance-relevant information encompasses how learners interpret their learning trajectory: it includes the performance of others, assessment outcomes, and responses of peers (van der Leeuw et al., 2018).

There are various learning theories underpinning feedback research and practice. Cognitivist approaches emphasize information-processing in that individuals receive feedback inputs, process them, and act to close gaps between current and desired

performance levels (Thurlings et al., 2013). Social constructivist feedback research takes the perspective that shared and individual interpretations are developed through dialog, sense-making, and through co-construction between participants (Price et al., 2011). Sociocultural approaches to feedback highlight the role of participation and meaning-making mediated through activity within social and cultural contexts embedded in the norms of different disciplines (Esterhazy and Damşa, 2019). Socio-material approaches suggest that feedback practices are entangled with social, material, spatial and temporal influences which may impede productive student involvement (Gravett, 2020).

In the last 15 years, there has been a significant increase in attention afforded to feedback in undergraduate education, and corresponding expansion of the research base. Two significant inter-related developments within the new paradigm of feedback are worth noting. The first focuses on feedback impacts in that the core of feedback processes lies in their impact on students, how learners improve their work or learning capacities. This line of thinking places particular emphasis on the closing of feedback loops, and evidence that students have used feedback information for enhancement (Boud and Molloy, 2013; Carless, 2019; Henderson et al., 2019). The second key development is in conceptualizing and researching student feedback literacy: the capacities to make sound academic judgments and work with feedback information so that it produces useful impacts (Carless and Boud, 2018). Unless students are developing a set of capabilities to engage productively in feedback processes, inputs may not lead to impact.

The aim of this chapter is to illustrate how new paradigm feedback practices can be implemented in undergraduate education in order to produce feedback impact and the development of student feedback literacy. Five inter-related sub-themes are discussed: partnerships in feedback literacy; feedback seeking strategies; peer feedback; digitally-enabled feedback; and feedback in online learning environments. For each of these sub-themes, key rationales, challenges and further possibilities are addressed.

Partnerships in teacher and student feedback literacy

Feedback literacy has been a focus of vigorous research interest in the last five years or so, driven by the appreciation that effective feedback processes rely on the capacities that students bring to the feedback partnership as well as the support provided by teachers. In their heavily cited paper, Carless and Boud (2018) defined student feedback literacy as the understandings, capacities and dispositions needed to make sense of information and use it to enhance work or learning strategies. Key frameworks suggested that student feedback literacy principally involves seeking, generating, engaging and using feedback; the development of capacities in making academic judgments; and acknowledging and working with emotions (Carless and Boud, 2018; Chong, 2021; Molloy et al., 2020). Emotional and relational support is a pre-requisite for opening oneself to critique, revealing vulnerability and engaging with hard-hitting commentary (Steen-Utheim and Wittek, 2017). Feedback literate individuals are able to maintain emotional equilibrium and avoid defensiveness when receiving critical feedback (Carless and Boud, 2018). Feedback interactions seem to work best within supportive relationships, although these kinds of close relationships are often hard to build and maintain within massified higher education.

How feedback literacy is manifested within different disciplines is an important consideration. The social norms and dynamics of different disciplinary learning activities entail various socioculturally-based affordances and constraints for the emergence of productive feedback exchanges (Esterhazy, 2018). A study of National Qualifications Frameworks and Subject Benchmark Statements, drawing on data from 6 countries, suggests that discipline-specific feedback literacies can be developed through authentic learning activities and assessment tasks (Winstone et al., 2020a). These resonate with the concept of authentic feedback, mirroring the feedback practices of the discipline, profession or workplace (Dawson et al., 2021). Building on the notion of signature pedagogies, the characteristic ways feedback processes are carried out in specific disciplines are represented by the concept of *signature feedback practices* (Carless et al., 2020; Quinlan and Pitt, 2021). Signature feedback practices are potentially valuable in integrating disciplinary ways of thinking with authentic and motivating feedback experiences (Carless et al., 2020).

The initial focus of feedback literacy research mainly focused on the student contribution in line with the orientation of new paradigm feedback practices. There are risks, however, that a focus on individual learner capacities neglects socio-material factors and assumes more agency than students possess within neoliberal mass higher education (Gravett, 2020; Nieminen et al., 2021). There is still, however, potential for feedback literacy to be developed through shared responsibilities between teachers and students, working in partnership toward common goals of enhancing student learning (Matthews et al., 2021; Nash and Winstone, 2017). Accordingly, teacher feedback literacy has begun to become a research focus because unless teachers facilitate opportunities for students to experience using feedback productively, student development of feedback literacy may be constrained. In an initial conceptualization of teacher feedback literacy, Carless and Winstone (2020) proposed a framework of three dimensions: a design dimension focusing on designing feedback processes for student uptake; a relational dimension representing the interpersonal side of feedback exchanges; and a pragmatic dimension addressing how teachers manage the compromises and workload implications inherent in disciplinary and institutional feedback practices. In an empirically-derived framework, Boud and Dawson (2021) added macro (program design and development), meso (course design and implementation) and micro (student assignments) levels of activity. Yet teacher feedback literacies may also involve learning to negotiate institutional structures, socio-material considerations, and power relations that influence or constrain new paradigm feedback practices (Tai et al., 2021).

To sum up this sub-theme, student and teacher feedback literacy represents the capacities to make the most of feedback opportunities. The co-ordinated interplay between teacher and student feedback literacy represents a promising means of tackling the challenges of reaping learning gains from feedback processes. Ongoing research might continue teasing out disciplinary differences

in feedback literacies and involve research and development projects focused on the mutual development of teacher and student feedback literacy. The publication in November 2021 of the first student feedback literacy scale (Zhan, 2021) also promises a new line of quantitative inquiry into feedback literacy.

Feedback seeking strategies

If students are to adopt a pro-active role in feedback processes congruent with new paradigm feedback practices, they need to elicit comments from suitable others and continue dialog with them as necessary (Carless and Boud, 2018). Eliciting feedback information on self-identified priority areas forms part of the characteristics and repertoire of feedback literate students. Feedback seeking behaviors are defined as learners intentionally eliciting information about their own work for the purposes of improvement. Feedback seeking is a key element of student self-assessment because it enables learners to calibrate and refine their own judgments (Yan and Brown, 2017; Yan and Carless, 2021). Feedback seeking has been somewhat under-explored in research on higher education pedagogy, although there are significant strands in relation to the workplace (e.g., Anseel et al., 2015) and in medicine (e.g., Bok et al., 2013).

The literature identifies two main forms of feedback seeking strategies: inquiry and monitoring (Leenknecht et al., 2019). Inquiry involves directly eliciting comments from others on progress or self-identified issues, either spontaneously or after being prompted by a teacher. These kind of feedback requests begin a dialog which potentially creates the conditions for effective feedback exchanges. The inquiry function is illustrated through students seeking comments on selected aspects of their work, thereby enabling teachers to tailor all or part of their input to students' preferences and perceived needs. Malecka et al. (2020) proposed that feedback requests should be embedded purposefully within the curriculum in cumulative ways so that eliciting becomes increasingly sophisticated with students adjusting requests in the light of ongoing progress. Teachers can model and encourage feedback seeking strategies because sometimes students are wary of eliciting feedback because they are wary of appearing too needy or revealing their limitations, and/or because they are worried about potential threats to their self-esteem if the response is critical. Supportive course cultures and trusting relationships create a climate to encourage feedback requests in which admitting doubts through eliciting information from others is a normalized aspect of pedagogy.

The second strand of feedback seeking strategies involves monitoring: drawing on information available in the environment, such as making comparisons with the previous performance of oneself or others, exemplars, assessment criteria, or consulting other resources deemed relevant. This form of feedback seeking stimulates internal feedback through interpreting cues or evidence. Monitoring is an aspect of feedback literacy in that it involves learners seeking cues from the environment, the assessment task criteria and exemplars (Joughin et al., 2021; Molloy et al., 2020). A further aspect of monitoring involves drawing on previous performance and related feedback to consolidate inferences for current and future development. The feedback literate student synthesizes previous comments from a wide range of sources to inform current performance.

To sum up this sub-theme, feedback seeking exemplifies new paradigm feedback practices in highlighting the active student role in feedback processes. Capacities to elicit feedback from others and continue interactions with them, where necessary, are part of feedback literacy. In terms of ongoing research, the knowledge base would benefit from more evidence of how students use feedback seeking strategies to enhance their work or approaches to learning.

Peer feedback

Peer feedback, also known as student peer review, involves learners evaluating and making judgments about the work of peers on a task that they have already attempted (Nicol et al., 2014). The main benefits from being exposed to the work of peers arise from the internal feedback generated when students make comparisons between their own production and that of others (Nicol, 2021). Through being exposed to a variety of work of different styles and standards, feedback literate students develop a sense of what quality work looks like. As they enhance their awareness of quality, and apply insights to their own work, students develop capacities in monitoring their own work in progress. These are enhanced when teachers design opportunities for digitally-mediated dialogs where students have opportunities to clarify peer feedback and co-construct opportunities to use it (Wood, 2022).

While well-implemented by some teachers, peer feedback is often carried out in sub-optimal ways and a number of challenges commonly arise (Winstone and Carless, 2019). Students sometimes worry that they or their classmates lack sufficient knowledge or competence to provide useful feedback. They may also find that some classmates do not engage seriously in composing peer feedback or that their efforts in offering constructive comments are not reciprocated. Students are also generally wary of forms of peer assessment which involve the award of grades because of concerns about unfairness and bias. By potentially disrupting some of the power dynamics of teacher-dominated feedback, peer feedback also faces socio-political challenges (Tai et al., 2021). Skillful designs of peer feedback sequences in the hands of feedback literate teachers potentially mitigate some of these challenges.

A significant, but frequently underplayed, aspect is the need for coaching in carrying out peer review as it cannot be assumed that students understand its principles and how to do it well. Coaching can include: explaining the rationale for peer feedback and its potential benefits; teachers modeling their experiences of academic peer review and strategies for managing the emotional impact of critical feedback; supporting students to generate and apply criteria; and advising them on how to carry out peer review more effectively (Carless and Boud, 2018). A key point is that the composing of peer feedback is often more beneficial than receiving

comments because it is a rich process of diagnosing problems and suggesting actionable solutions (Nicol et al., 2014). Whenever possible, multiple peer reviews should be arranged so that students can be exposed to work of different quality and receive more than one commentary on their work (e.g., Harland et al., 2017). This prepares the ground for students to make comparisons between their own work and that of others (Nicol, 2021).

To sum up, peer feedback is a complex lifelong learning capacity that needs sustained and cumulative practice over time. Designing effective peer feedback sequences and supporting students in involving themselves productively are elements of teacher feedback literacy. Composing peer feedback and learning from comparing one's own work with that of others are two of the most beneficial aspects of peer feedback processes.

Digitally-enabled feedback

Digitally-enabled feedback processes carry the promise of timeliness, convenience, and portability with the potential to streamline staff workloads and facilitate prompt feedback interactions with students even with large classes. Technology has considerable potential to enable promising feedback practices, especially when it is context, students' needs and pedagogical considerations which drive technology choices.

Building on the previous sub-section, technology is often deployed to facilitate student peer review, especially with large classes. PeerMark within the Turnitin suite of applications and Moodle Workshop for peer assessment enable the anonymizing of student submissions and automatic allocation of peer reviewers. Moodle Workshop features, such as scoring guides, were found to be particularly useful in facilitating formative peer feedback on draft essay assignments within a macro-economics class of 800 first year students (Mostert and Snowball, 2013). Challenges still arise, however, in terms of motivating students to engage in peer dialogs that go beyond perfunctory exchanges of low-level information.

Audio and video modalities enable the production of peer feedback. In a study of audio peer feedback within large online courses, it was found that providing and receiving audio feedback encouraged deep approaches to learning and a sense of commitment (Filius et al., 2019). Peer-to-peer audio or video feedback carry potential to promote student interaction, engagement, and the development of a learning community. Whereas teacher audio or video feedback risks perpetuating information transmission approaches (Mahoney et al., 2019), peer-generated variations potentially harness the active role of students in generating internal feedback and making judgments.

Digitally-enabled feedback of different forms can be implemented in various user-friendly ways. Online annotated exemplars can serve as proxies for teacher feedback by clarifying what good performance in a task looks like and acting as inputs which stimulate students to generate internal feedback and then enhance their own work (Carless, 2020). Collaborative exchanges involving peers and teachers facilitated through cloud applications enable learners to discuss feedback and use insights to revise work in progress (Wood, 2021). Electronic marking and feedback through tools, such as "Track Changes" or annotated PDF documents can sometimes be useful although they are mainly positioned as old paradigm transmission of information. When teacher inputs of this kind are designed to encourage self-regulation or invite student follow-up, they are moving in a new paradigm direction.

Recent developments in learning analytics make it possible to track a range of students' behaviors in digital learning environments, such as whether they have viewed a resource or opened a file of feedback comments, and the time spent on these activities. Information based on learning logs and digital traces can enable formative feedback for large cohorts to be delivered just in time for student action (Pardo et al., 2019). Research into the impacts of analytics-based feedback suggests that this kind of feedback can stimulate self-regulated learning by enabling students to adjust their learning strategies to optimize their performance (Lim et al., 2020). Learning analytics focuses on individual behaviors while tending to downplay other aspects, such as social and collaborative learning, so users of analytics-based data need to be aware that what can be traced through analytics is only part of a student learning trajectory (Fawns, 2019). When presented in a student-facing way, learning analytics does, however, offer potential in contributing insights into students' learning behaviors through providing information about facets of their own progress and in relation to other members of their cohort.

A promising example of digitally-enabled feedback is the Feedback Engagement and Tracking System (FEATS), a feedback e-portfolio which enables learners to synthesize feedback from various sources, and monitor their progress toward self-identified enhancement targets (Winstone, 2019). This e-portfolio involves a feedback review and synthesis tool where students collate multiple feedback inputs to identify focal areas for improvement; a bank of relevant resources such as videos, websites or articles to enable the development of self-identified target skills; and a student-generated personalized feedback implementation plan with tasks that need to be completed by certain dates. Through repeated review of feedback information and planning for uptake, students focus on how feedback supports their learning beyond an individual unit or task (Winstone and Carless, 2019). This signals the important and under-researched dimension of program-level approaches to feedback: how can students be supported to transfer insights across the courses that make up their entire undergraduate program?

To sum up this sub-section, digitally-enabled feedback is most productive when learners are involved actively in ways which support the development of their feedback literacy. Technology is harnessed most effectively when students' needs are at the forefront, and technology facilitates new paradigm feedback practices rather than just the transmission of information.

Feedback in online learning environments

Emergency online teaching during the COVID-19 pandemic has further placed the spotlight on online feedback possibilities. Many of the digitally-enabled possibilities discussed above are relevant but there are also some additional strategies or issues that merit consideration. Automated online quizzes, for example, are part of a flexible repertoire of online feedback methods and seem particularly popular in the hard sciences. These kinds of quiz seem to be most useful when hints rather than correct answers are provided to increase cognitive engagement (Förster et al., 2018). If students retake an online quiz on multiple occasions, reflect on previous performance, and/or access relevant resources, productive learning can accrue.

Social presence is important in reducing isolation of the online or distance learner and feedback interactions can play a role. In the previous sub-section, the potential of peer-to-peer audio or video feedback was highlighted and teachers can also provide commentary through video feedback to highlight key issues, and enhance social presence. Video feedback should probably be short and to the point in order to minimize cognitive load, and is more oriented toward new paradigm feedback practices when some kind of student response or follow-up is required. The qualitative synthesis by Mahoney et al. (2019) found, however, that few studies explicitly incorporated opportunities for dialog or response to teacher video feedback inputs, so the potential for social interaction was not fully exploited.

Screencasting tools enable teachers to provide audio and/or visual commentary on student work. A screencast is a digital recording that shows actions taking place on a teacher's computer screen. By capturing what is on teachers' monitors, screencasts can show as well as tell the teacher response to student work. A useful variation congruent with new paradigm feedback practices is for students to generate their own screencasts or respond to those of the teacher. In the context of a distance learning Spanish program, Fernández-Toro and Furnborough (2014) used screencasting to enable students to record their responses to feedback through thinking aloud for 5 min. This strategy enabled students to have time and space to reflect on feedback inputs and articulate their responses. It afforded dialogic interaction between students and teachers, and helped teachers see how students engaged with feedback. Screencasts can also be combined with cloud applications, such as Google Docs, to enable students to respond to and question inputs through digitally-mediated dialogs (Wood, 2021).

Learning management systems (LMSs) are probably not particularly well-designed to facilitate new paradigm feedback practices. Challenges for students include the timing and easy accessibility of feedback messages on the LMS, reinforcing difficulties of student engagement with these kinds of feedback and grading inputs (Winstone et al., 2020b). Low achieving students often did not access feedback when it was reported separately to the grade on the LMS, reinforcing a challenge for feedback practice that students most in need of feedback are least likely to engage with it (Mensink and King, 2020). With principled pedagogical adjustments, LMSs might become useful repositories for feedback information and students could be encouraged to show how they are using feedback from previous assignments to inform current submissions in analogous ways to FEATS above. Discussion forums on LMSs could, in principle, enable students to involve themselves in dialogs around course content or work in progress but in practice students often do not seem to find these asynchronous written discussions particularly motivating, user-friendly or engaging. If well-designed, discussion forums might generate useful feedback exchanges but they need to enable student agency and interaction so that they do not just end up as busy work that does not contribute to substantive course assessment outcomes.

Social media, such as Facebook or Twitter are increasingly being used for academic interaction and may be particularly useful in online learning environments. There is potential to capitalize on the ubiquity of social media by integrating feedback exchanges. A challenge, however, lies in bridging interpersonal and academic domains by using a predominantly social platform for learning purposes. An implication is that participating in these kinds of feedback exchanges might be a voluntary option rather than a compulsory course element. Under these circumstances, there is potential in social media for facilitating collaborative learning and feedback dialogs.

To sum up this sub-section, online feedback needs to be carefully planned and designed so that inputs go beyond than unidirectional transfer of information in old paradigm ways. Future research and development work might aim to investigate the intersection between new paradigm feedback practices and online feedback, and the teacher and student feedback literacies required for successful implementation.

Conclusion

Feedback is a complex social interaction which carries implications for well-being and self-esteem. Effective feedback processes rest on shared responsibilities between participants within cultural and disciplinary contexts. This perspective resonates with new paradigm feedback practices in highlighting active student roles in seeking, generating, processing and using feedback information. The potential value of digital feedback possibilities has been an area of focus for some time, but marrying the digital with purposeful feedback designs and the co-development of teacher and student feedback literacies remains a key aspect for further exploration.

Introduction

Ancient philosophers such as Aristotle, Socrates and Jean-Jacques Rousseau believed that students do not learn by being told. Knowledge, in their view, is constructed through active and curiosity-driven processes of observation and reasoning. These sentiments echo in the writings of American psychologist John Dewey (1900, 1938), who planted the seed for the instructional method currently known as inquiry-based learning. Dewey argued that teachers should create opportunities for students to discover for themselves, and guide them in the process of becoming active and independent learners. More recent influential scholars such as Jean Piaget and Jerome Bruner provided the first empirical support for Dewey's philosophical propositions by showing how and under which conditions people learn through self-directed explorations (Bruner et al., 1956; Inhelder and Piaget, 1958).

Inquiry-based learning has become a common instructional method in many countries, although its application varies depending on the educational level and definitions used. In science education, which is the main focus of this article, the method is defined as one in which "students investigate scientifically oriented questions, conduct experiments, formulate explanations based on evidence, evaluate their explanations in light of alternative explanations, and communicate and justify their proposed explanations" (National Research Council, 2000, p. 25). These activities are often combined in a so-called inquiry cycle that generally consists of five phases (Pedaste et al., 2015). In the orientation phase, students explore the topic of investigation, for example by reading introductory texts or making initial observations. During the conceptualization phase, students generate one or more research questions and formulate hypotheses, which they test through observation or experimentation during the investigation phase. The data that result from these investigations are interpreted during the conclusion phase where students decide on the validity of their hypotheses or develop new ideas. In the final discussion phase, students look back on their inquiry and communicate their findings.

Inquiry-based lessons do not necessarily include all of these activities. Teachers can, for example, decide to take over or skip activities that are too difficult or time consuming. As a result, inquiry-based lessons can take many forms and range from highly teacher directed to highly student centered (Furtak et al., 2012). Bell et al. (2005) proposed a four-level framework to evaluate instructional activities in terms of the amount of inquiry students perform themselves. At level 1, the lowest level of inquiry, students investigate a teacher-given question using a prescribed procedure to confirm a known outcome. At level 2, the activity is slightly more open in that the outcome is unknown to students in advance. Inquiry tasks at both these levels prevail in textbook-based curricula (Chinn and Malhotra, 2002) and are sometimes mockingly referred to as "cookbook science". At level 3, only the research question is given so students have to design and conduct their own investigations, whereas level 4 activities are completely open in the sense that research questions, methods and outcomes all have to be conceived by the students.

A well-designed curriculum gradually exposes students to more open forms of inquiry (Bell et al., 2005). This learning progression assumes that students become increasingly more adept in doing research, which is indeed a main goal of inquiry-based learning. However, not all students succeed in improving their inquiry skills and even the ones who do, tend to struggle during a self-directed investigation. So in addition to selecting a level of inquiry, teachers should assist students in order for inquiry-based learning to be effective, and recent research suggests that this guidance should be adapted to the needs of individual students. These issues of student readiness, guidance and differentiation form the backbone of this article. They are discussed in more detail in the sections below, with a main emphasis on the inquiry skills employed in elementary and secondary science classrooms. This is not to say that inquiry-based learning is exclusively meant for science education; the method has been successfully applied in other school subjects such as economics (Grol et al., 2016) and history (Reisman, 2012; Voet and De Wever, 2017), but these applications are beyond the scope of this article.

An example of inquiry-based learning

An example from an elementary school science project developed by the Science Education Hub Radboud University (Dekker and Van Baren-Nawrocka, 2017) illustrates inquiry-based learning in action. The sixth-graders in this example were first introduced to molecular collisions, which was the topic of inquiry, by observing how long it takes for colored ink to dissolve in hot and cold water. Following a teacher-led discussion of the findings, the children started thinking of a research question. One group decided to investigate how temperature affects the application of paint. They hypothesized that warm paint is more spreadable than cold paint because its molecules move faster. To test this idea, the children asked ten classmates to apply three samples of paint on a sheet of paper and indicate on a 3-point scale how well each one spread. The paint samples differed in temperature while all other materials were kept the same. When the ratings were displayed in a table, the children noticed a clear pattern in scores: paint from the fridge (7 °C) was perceived less spreadable than paint at room temperature which, in turn, was regarded less easy to spread than paint heated to 50 °C. These results confirmed children's hypothesis: warm paint is indeed more spreadable than cold paint. They presented this conclusion on a science fair poster, together with a brief description of their hypothesis, procedure, materials and results.

The children's teacher had a supportive role in every phase of the inquiry. She planned each activity and monitored progress to ensure that all groups would finish in time. In addition to this regulative support, the teacher helped pupils with the procedural parts of the inquiry, for instance by checking whether research questions were feasible and hypotheses testable, suggesting ways to set up a good experiment, explaining how data can be presented in a table, and so on. Although some of this guidance was available through worksheets, the teacher was on standby to offer ad hoc assistance where needed. She also offered content support at the beginning and end of each lesson to activate children's prior knowledge and discuss the learning experiences in light of molecular collisions. And on top of that, she took care of all practical arrangements. Her continuous and substantial guidance enabled children to successfully complete an open inquiry (i.e., "level 4" according to the framework of Bell et al., 2005) that would otherwise be beyond their reach.

Conditions for inquiry-based learning

Not every topic lends itself well to inquiry-based learning. Plain facts (e.g., there are 2.54 cm in an inch) and simple operations (e.g., $2 + 2 = \dots$) leave little room for scientific investigation and are probably best taught through didactic methods. But when the learning content is more ill-structured or open to multiple interpretations, inquiry-based learning can foster a deep understanding. A good topic for inquiry encourages students' curiosity and enables them to pose research questions and hypotheses to test their initial beliefs. Although it may sound paradoxical, an inquiry is generally more effective if students enter the classroom with some prior knowledge of the topic of investigation—regardless of its truthfulness—as this will help generate hypotheses and provide a focus for the inquiry (Lazonder et al., 2008; Lazonder et al., 2009). In other words, domain knowledge facilitates the use of inquiry skills.

Inquiry skills, like the ones exemplified in the previous section, generally start developing in Kindergarten. Four-year-olds display an initial proficiency in experimentation and evidence evaluation (Koerber and Osterhaus, 2019; Lapidow and Walker, 2020; Van der Graaf et al., 2018) whereas the more difficult skill of hypothesizing emerges around age 12 (Kuhn et al., 2009; Piekny and Maehler, 2013). Still, the development of all skills is rather slow and erratic, and differs considerably among same-age children (Lazonder et al., 2021; Schlatter et al., 2020). These developmental differences might explain why some high school students still face problems during a self-directed investigation (Krajcik et al., 1998; Mulder et al., 2010)—but it could also be that these students fail to apply their learned inquiry skills when left on their own account. So the bottom line is that students of all ages are ready for inquiry-based learning, but need help from their teachers to make their investigations productive for learning.

As teachers are the key element in inquiry-based classrooms, it is problematic that many of them find inquiry-based learning demanding and difficult to implement in their lessons (Dobber et al., 2017). Those capable of successfully applying the method possess certain attitudes and skills to promote student learning. Research suggests that these teachers have rich content knowledge and hold the epistemological belief that inquiry is a quest for meaning rather than a test to determine if something works or a set of pre-determined activities that lead to a known outcome. Successful teachers also use well-vetted strategies to guide students through the phases of the inquiry cycle, including ways to encourage their curiosity, promote productive classroom discourse and develop a culture of inquiry (Danielsson and Warwick, 2014; Dobber et al., 2017; Yoon et al., 2012).

Criticisms of inquiry-based learning

Although inquiry-based learning has enjoyed widespread support by educational policy makers and field experts, opinions in the scientific community are divided (see, for an overview, Zhang, 2016). Back in the 1960s, scholars such as Ausubel (1962) considered the method—which, at the time, was called "discovery learning"—to be developmentally appropriate for children in the concrete operational stage; older learners capable of formal operational reasoning should be taught by expository methods, which back then were deemed more effective and efficient. More recently, Klahr and Nigam (2004) fanned the flames by showing that even pupils in third and fourth grade learn more from interactive teacher demonstrations than through unguided discovery. Based on

a historical analysis of the effectiveness of such unguided discovery methods, Mayer (2004) argued against what he called “pure discovery learning” and in favor of more guided methods of instruction. A similar argument was raised by Kirscher et al. (2006), who based their objections on the limited processing capacity of the human brain. When students have to find things out on their own, the processing demands on working memory become so high that there is little cognitive capacity left for the actual learning of new information.

Hmelo-Silver et al. (2007) replied by demonstrating that Kirschner et al. (2006) confounded inquiry-based learning with unguided discovery learning. Hmelo-Silver and colleagues argued that in practice inquiry-based activities are often heavily guided—or scaffolded as they called it—in order to reduce cognitive load and facilitate student learning. This guidance can take many forms and does not necessarily have to precede the inquiry. Rather, effective guidance can just as well be, and often is, embedded in the activity itself. This reply set the research agenda for the next decade and inspired many scholars to start examining the effectiveness of different types of guidance during inquiry-based learning (e.g., Hagemans et al., 2013; Kuhn and Katz, 2009; Lazonder and Kamp, 2012; Morgan and Brooks, 2012).

Meanwhile, outcomes of international benchmarking studies such as the Program for International Student Assessment (PISA) and Trends in International Mathematics and Science Study (TIMSS) fueled the debate over the value of inquiry-based learning. For example, Kaya and Rice (2010) showed that the frequency of inquiry-based lessons was negatively associated with elementary schoolchildren’s scores on the science items of the TIMSS 2003 assessment. More recently, Jerrim et al. (2019) analyzed the PISA 2015 dataset and found that the frequency of inquiry-based learning was negatively associated with English teenagers’ PISA test scores (cf. Oliver et al., 2019). These findings might be interpreted as disqualifying inquiry-based learning as an effective way of teaching scientific knowledge. Such criticism should nevertheless be interpreted with caution because the TIMSS and PISA data merely convey how often students were exposed to inquiry-based learning. As it remains unknown which activities students engaged in and how much guidance they received, the comparability and accumulation of results across schools and countries remains problematic (Rönnebeck et al., 2016) and points to a need for more systematic comparisons of the effects of guidance.

Guidance to facilitate inquiry-based learning

The relative effectiveness of instructional methods has intrigued educational scientists for many years and inquiry-based learning has often been included in their comparative analyses. While individual studies contrasting two or more instructional methods often fail to provide rigorous evidence due to a lack of experimental control (see, for an exception, Eysink et al., 2009; Martella et al., 2020), meta-analyses synthesizing the results of these studies are generally considered a powerful means to establish true effects and estimate their magnitude. In one such research integration, Alfieri et al. (2011) concluded on the basis of 164 primary studies that unguided inquiry-based learning is less effective than direct instruction. The Cohen’s d effect size estimate indicated that posttest scores were 0.38 standard deviation higher for students who learned the same material through direct instruction, which represents a medium effect. This result clearly undergirds the argument presented by Mayer (2004) and Kirschner et al. (2006) that unguided discovery is ineffective. However, the second part of Alfieri et al.’s meta-analysis compared expository methods such as direct instruction with guided inquiry-based learning and found favorable results for the latter, again with a medium effect size ($d = 0.30$). In other words, inquiry-based learning is effective if adequately guided.

But what exactly does “adequate guidance” entail? One answer that immediately comes to mind is that students should receive sufficient guidance to be able to complete their inquiry and learn from the activity. A meta-analysis by Furtak et al. (2012) confirmed that the amount of guidance makes a difference. Participants of the 37 synthesized studies tended to learn more from a minimally guided inquiry than through expository instruction, but the magnitude of this effect was more than doubled in situations where teacher guidance was intensified. This evidence, although insightful, is of course one piece of the puzzle (cf. Vorholzer and Aufschneider, 2019). Questions remain regarding whether guidance should focus on the content or the procedural part of the inquiry, whether the specificity of the guidance matters, and whether the effectiveness of giving more or more specific guidance depends on the students’ age and experience.

These questions were addressed in a meta-analysis by Lazonder and Harmsen (2016), who synthesized 72 studies on inquiry-based learning in science and mathematics education. The authors based their categorization of guidance on a taxonomy originally proposed by De Jong and Lazonder (2014), which comprises six types of guidance that differ in terms of specificity or explicitness. As shown in Table 1, these types of guidance become increasingly more specific and were therefore assumed to suit the needs of learners with increasingly less inquiry skills. In line with Hmelo-Silver et al. (2007), all types of guidance can be provided by the classroom teacher, but (part of) it can also be offered by curriculum materials, educational software, teaching assistants, or classmates.

All studies included in Lazonder and Harmsen’s (2016) meta-analysis contrasted a group of students who received some kind of guidance during an inquiry task against a group of students who performed the same task without this guidance. Results showed that, overall, guidance empowered students’ inquiry skills during the task, enhanced the quality of the artifacts they created (e.g., lab reports, science fair posters), and increased learning outcomes as assessed by a posttest. Effect sizes were in the range of 0.50–0.71 and differed considerably across studies. Contrary to expectations, this variability was largely independent of the type of guidance. Although this finding might seem counterintuitive—it might be assumed that more specific guidance produces larger effects—the taxonomy in Table 1 presents a possible explanation: more specific guidance is intended for younger, less experienced students so the net effect could be the same. To test this possibility, Lazonder and Harmsen examined whether the effectiveness of the types of

Table 1 Taxonomy of guidance for inquiry-based learning.

<i>Type of guidance</i>	<i>Basic idea</i>	<i>Intended audience</i>
Process constraints	Restrict the comprehensiveness of the learning task	Learners who are able to perform and regulate the basic inquiry process, but still lack the experience to do so under more demanding circumstances
Status overviews	Make task progress or learning visible	Learners who are able to perform the basic inquiry process, but lack the skills to plan and keep track of their learning trajectory
Prompts	Remind to perform an action	Learners who are able to perform an action but may not do so on their own initiative
Heuristics	Remind to perform an action and suggest how to perform that action	Learners who do not know exactly when and how an action should be performed
Scaffolds	Explain or take over the more demanding parts of an action	Learners who do not have the proficiency to perform an action themselves or cannot perform the action from memory
Explanations	Specify exactly how to perform an action	Learners who are (largely) incognizant of the action and how it should be performed

Note. From: Lazonder, A.W., Harmsen, R., 2016. Meta-analysis of inquiry-based learning: effects of guidance. *Rev. Educ. Res.* 86, 681–718.

guidance listed in [Table 1](#) varied for different-aged students. This was not the case: children, teenagers and adolescents were equally responsive to any particular type of guidance. These findings contradict the assumed match between the specificity of guidance and students' prior knowledge and skills, and leaves unanswered the question why more specific guidance is not more productive for learning.

To conclude, there is a vast body of evidence demonstrating that guided inquiry-based learning is more effective than expository methods of instruction. Researchers have therefore started to examine the role of guidance in more detail but these attempts have thus far failed to provide a solid understanding of “what works when and why”. One possible reason is that the lion's share of these studies administered one type of guidance to groups of peers. As students of the same age, and even in the same classroom often differ considerably in terms of general cognitive abilities and readiness for inquiry-based learning, a paradigm shift toward more differentiated forms of guidance might be needed to understand how teachers can support students' inquiry in more effective ways.

Differentiated guidance to optimize inquiry-based learning

[Koerber et al. \(2015\)](#) examined what second-, third- and fourth-graders know about “doing research”. The results of this cross-sectional study implied that children gradually develop a more advanced understanding of scientific inquiry, but occasionally fall back on more naïve conceptions. This inference was generally confirmed in a three-year longitudinal assessment ([Lazonder et al., 2021](#)), which additionally revealed substantial individual variation in children's development of inquiry skills. Some low-performing children in this study hardly made any progress throughout the years, whereas others managed to improve their proficiency scores from 7 to 87% on a performance-based inquiry-skills test. This overall progress does not apply equally to all inquiry skills. Experimentation skills, for example, are generally learned rather quickly whereas the skills of hypothesizing and evaluating evidence require more than a single lesson series to improve ([Schlatter et al., 2020](#)).

This snapshot of the developmental psychology research serves to illustrate the sizable individual differences among students and across inquiry skills. Accommodating these differences is a promising way to make inquiry-based learning more effective, and requires abandoning the “one size fits all” approach in favor of more differentiated forms of guidance. Research suggests that these adaptations can be planned in advance based on students' proficiency in language and math as well as their performance in previous school inquiry projects. Language and math achievements are reliable sources of adaptation because of their consistent positive association with students' performance on inquiry tasks (e.g., [Koerber et al., 2015](#); [Lazonder et al., 2021](#); [Schlatter et al., 2020](#); [Van der Graaf et al., 2018](#)). Other cognitive and demographic characteristics such as intelligence, executive functioning, gender and socioeconomic status have a less determinate influence and are therefore a less reliable source.

The taxonomy presented in [Table 1](#) provides suggestions for how guidance can be differentiated to meet the needs of individual students. Teachers could, for example, decide to offer experimentation prompts to the more advanced students in their class (e.g., “remember to design a well-controlled experiment”), heuristics to the average achievers (e.g., “remember to design a well-controlled experiment, so only vary the variable you want to find out about”) and full-fledged explanations about experimental design procedures to students who are expected to struggle most. This example illustrates what [Tomlinson \(2001\)](#) referred to as “differentiation in process”. Differentiation can also target the learning content, for instance by having advanced students investigate more difficult

research questions; the products students create to demonstrate their learning; or the learning environment, which is often synonymous to grouping arrangements in collaborative classrooms.

Eysink et al. (2017) exemplified how these differentiation modes can be combined in an inquiry-based classroom. Pupils in this study collaborated in groups of four to investigate elementary school physics themes such as magnetism, buoyancy and sound. Each theme comprised four topics that differed in complexity, and pupils were assigned to a topic that matched their ability level (as determined by a pretest). The better-achieving children, in addition, received coarse-grained written directions to perform their part of the inquiry, whereas stepwise instructions were given to the lower-achieving children. Teacher assistance during the lessons was adapted accordingly, meaning that more specific guidance was given to lower-achieving pupils and vice versa. Toward this end, group composition changed periodically from heterogeneous ability groups (where students could help each other) to homogeneous ability groups (where the teacher could give ability-matched support).

This example indicates that differentiated guidance does not stand on its own as it should align with instructional decisions regarding the learning content, the products students create and the arrangement of the learning environment. This “balancing act” is one of the reasons why many teachers find it difficult to differentiate their lessons (e.g., Gaitas and Alves Martins, 2017) and often refrain from trying. Those who do succeed possess sufficient domain knowledge, have adopted a growth mindset and reflect on their own teaching (Parsons et al., 2018). These inherent teacher characteristics match the conditions for successful inquiry-based learning presented earlier and develop from experience and through formal training. The merits of differentiation training were demonstrated by Vogt and Rogalla (2009), who offered elementary and secondary science teachers a two-day seminar and nine follow-up coaching sessions to help apply learned differentiation strategies in class. The participating teachers were found to exhibit superior differentiation behavior compared to teachers from an untrained control group, and their students learned more from the differentiated science lessons than students in the control classes.

These findings can be summarized in a punny phrase: “teachers need guidance to differentiate their guidance”. This was also one of the conclusions from an unpublished systematic review of differentiation practices in language, math and science education (Lazonder, 2018). Across the 32 synthesized studies, continual support was found to be more effective than initial support (i.e., just an introductory training), which, in turn, was as ineffective as no teacher support at all. A lack of teacher support was probably the main reason why the integrated differentiation approach of Eysink et al. (2017) failed to enhance student learning. Studies that continued to coach and assist teachers during differentiation proved more successful (e.g., Mastropieri et al., 2006; McCrea Simpkins et al., 2009).

The difficulties teachers anticipate or encounter with differentiation can be circumvented by embedding guidance in learning materials or the learning environment. Such adaptive guidance is becoming increasingly popular in software applications for language and math learning, and is beginning to find its way into science education research. For example, Neubrand et al. (2016) adapted the prompts tenth-graders received during an online evolutionary biology lesson based on pretest scores. Contrary to expectations, students did not learn more when supported by ability-matched prompts. In a more successful attempt using the Go-Lab online learning environment, a software agent generated adaptive feedback on the hypotheses middle school students’ drafted while investigating electrical circuits. Students who consulted this feedback were much more likely to create syntactically correct hypotheses than those who ignored it (Kroeze et al., 2019). Still, studies investigating differentiation in science education are remarkably scarce. Researchers should therefore devote more attention to this important topic in order to unveil how science teachers can guide students’ inquiry in more effective ways.

Conclusion

The research reviewed in this article paints an optimistic portrait of inquiry-based learning. Although not without criticism, the method can certainly be more effective than expository forms of teaching and learning—if used thoughtfully. Teachers who successfully apply inquiry-based learning in their classrooms ensure that their students have some initial understanding of the topic of investigation and offer appropriate guidance to compensate for anticipated and observed skill deficiencies. This guidance should preferably be attuned to the needs and preferences of every single student, which admittedly puts high demands on the teacher. Distributing the guidance across curriculum materials, educational software and even fellow students could be a fruitful way to alleviate this burden.

In a broader perspective, inquiry-based learning belongs to a family of student-centered approaches that all share a focus on active learning, which is rooted in the belief that knowledge is constructed from experience. Related approaches relevant to the field of science education include design-based learning (e.g., De Jong et al., 2010), model-based learning (e.g., Mulder et al., 2015) and problem-based learning (e.g., Hmelo-Silver et al., 2018). All these approaches include some form of student research that generally follows the steps in the inquiry cycle, although minor variations exist due to the purpose of the activity: designing an artifact or solving a problem requires a slightly different research approach than investigating scientifically oriented questions. Conversely, models of inquiry-based learning also include elements of other instructional approaches discussed in this section of the encyclopedia, such as collaborative learning (students often conduct their inquiry in dyads or small groups) and argumentation (students evaluate evidence in order to draw conclusions).

Computer simulations and virtual labs are gaining momentum in inquiry-based science classrooms. These technological applications have some clear advantages over experiments performed with “real” materials in the school lab, such as shorter preparation time, increased safety and the production of clean datasets. Research has shown that both experimentation modes have a similar

positive effect on students' acquisition of conceptual knowledge and inquiry skills. Virtual and real experiments can also be combined, for instance by having students explore a topic through simulation-based experiments before entering the school lab. Alternating this sequence so that lab experiments precede simulation work is equally effective, thus offering teachers the possibility to combine virtual and real experiments based on practical considerations (Kapici et al., 2019; Lazonder and Ehrenhard, 2014; Zacharia, 2015).

Technological advances also open new opportunities for offering and differentiating student guidance. Rather than placing this responsibility entirely in the hands of the teacher, intelligent software agents could monitor students' ongoing activities and provide tailor-made support, either on demand or automatically on a just-in-time basis. Such blended learning environments are currently within reach and raise the question as to how guidance should be distributed across teachers and adaptive software agents. Pedaste et al. (2016) envisioned a scenario where the two act in symbiosis: software agents could handle the more straightforward needs for guidance while the teacher takes care of the more intricate issues. Although software agents may eventually be capable of fully taking over the role of the teacher, this option is still beyond reach—and one may wonder whether the complete absence of a human teacher is in fact desirable for social and motivational reasons.

Another topic worthy of consideration is the domain-general nature of inquiry skills. Most models of inquiry-based learning are loosely based on the "scientific method": a highly generalized portrayal of how knowledge is constructed by the scientific community rather than a description of what individual researchers actually do. As research practices vary across scientific disciplines (Dunbar, 2000), students should be familiarized with these domain-specific idiosyncrasies. This argument is central to the Next Generation Science Standards (NGSS Lead States, 2013) in the US, but other countries still seem somewhat hesitant to embrace this science-as-practices vision. From an instructional perspective, one may wonder whether a disciplinary approach to scientific inquiry is always desirable. Young learners, for example, might benefit more from repeated engagement with the same, generic model of inquiry; the non-unitary perspective becomes relevant once a solid basic understanding is reached. Questions like these are discussed at length in the volume edited by Fisher et al (2018).

Many other works dealing with or touching on inquiry-based learning have been published over the past decade, and their disciplinary focus demonstrates that inquiry-based learning remains a timely topic in science education (e.g., Trundle and Saçkes, 2015; Tsivitanidou et al., 2018). The uptake in other content areas lags behind, but perhaps the emerging emphasis on disciplinary differences in scientific inquiry could serve as a catalyst for a broader application. Schools aspiring to increase the frequency of student inquiry throughout their curriculum are recommended to develop a coherent rationale for when and how the domain-general and domain-specific aspects of inquiry will be addressed, and establish a dialog between teachers of different subjects to materialize this vision in lesson materials. Initiatives like these will enable educational researchers and practitioners to join forces in working toward increasing the scientific literacy of our future generations.

Computer-based training (CBT) systems are digital technologies that range from digital books that are read by learners at their own pace to adaptive systems that follow simple learning principles at a course-grain level. For example, in a typical adaptive CBT that applies mastery learning, the student (a) studies material presented in a lesson, (b) gets tested with a multiple-choice test or other objective test, (c) receives feedback on the test performance, (d) re-studies the material if the performance is below a mastery threshold, and (e) progresses to a new topic when done.

Intelligent tutoring systems (ITSs) are more advanced digital environments that help students master dozens-to-hundreds of specific knowledge and skill components by implementing intelligent computational procedures that adapt to students at a fine-grained level and that instantiate complex principles of learning (Graesser et al., 2018; VanLehn, 2006; Woolf, 2009). ITSs have traditionally worked with one student at a time in order to adapt to the idiosyncrasies of individual learners. However, recent ITS efforts have included team training that goes beyond a single individual to small groups (Sottolare et al., 2018a).

Conversational agents have been developed during the last 30 years to serve as substitutes for human tutors, teachers, peers, and students. Computer agents attempt to simulate text, speech, gestures, body movements, and/or facial expressions in ways similar to people, but may go beyond what humans do by implementing pedagogical mechanisms that humans cannot or do not provide (Graesser, 2020; Johnson and Lester, 2016). The agents are programmed to apply learning science principles systematically at varying degrees of complexity and grain size, with more reliability than humans. Inflexible conversational agents are aligned with CBT instruction when they present information in a rigid choreographed sequence and model ideal behavior, strategies, reflections, and social interactions. In contrast, intelligent agents are flexible because their behavior is adaptive to the learners' actions, verbal contributions, emotions, and/or other psychological states. For example, *AutoTutor* helps students learn by holding a dialogue in natural language (Graesser, 2016; Nye et al., 2014) or engaging in a three-way "trialogue" that has two agents (a student and a peer agent) interacting with the human learner (Graesser et al., 2017). *AutoTutor* conversations that analyze the meaning of students' verbal contributions are unique for each student.

This chapter covers advances in ITSs and conversational agents, with an emphasis on the intersection between these two technologies. Together these technologies have the promise of meeting the needs of education both in the past and into the future. The report on *How People Learn II* (HPL-II) of the National Academy of Sciences, Engineering, and Learning (NASEM, 2018) emphasized the uniqueness of individual learners in their background knowledge, culture, and contexts of learning. Therefore, educational activities need to shift from one-size-fits all to individualized instruction. The HPL-II report also emphasized the importance of digital technologies to provide broad and deep personalized instruction. The ITS environments provide this opportunity. Human instructors will of course be a major part of the future educational ecosystem as they have in the past. Most training over previous millennia has been one-on-one through an apprenticeship framework with conversations between the learner and a master, mentor, or tutor (Collins and Halverson, 2009). Print became popular after the printing press, particularly during the industrial revolution, because of its efficiency in dissemination and training. Nevertheless, one-on-one communication has continued to be mainstream. Conversational agents provide some facsimile of similarity to human interaction, and thereby fill this need when access to high quality human instruction is limited.

Intelligent tutoring systems

All ITSs adopt the principle of active student learning rather than resorting to the mere delivery of information through lectures, films, and books (Chi and Wylie, 2014; Lesgold, 2019). However, there is tremendous variation in the learning principles that are implemented in the different ITSs. One way of analyzing and classifying ITSs is to identify the “technological affordances” of the learning environments that were identified in the HPL-II report (NASEM, 2018). An affordance is a feature or property of the digital system that makes possible a particular way for the learner to use it. The following affordances nearly always occur in an ITS:

Interactivity. The system responds to actions of the student contingently, that is, it responds differently depending on what the student’s actions are.

Adaptivity. The system presents information and activities that are contingent on the knowledge, skills, abilities and other psychological characteristics of the student.

Feedback. The system gives feedback to the student on the quality of the student’s responses, including qualitative information that improves a correct response or corrects an error.

The following affordances frequently occur in ITSs but not always:

Choice. The system gives students options on what to learn in order to improve motivation and encourage self-regulation of learning.

Nonlinear access. The system allows the student to select or receive learning activities in an order that deviates from a rigid curriculum order.

Linked representations. The system provides quick connections between representations that emphasize different conceptual viewpoints and media, such as verbal descriptions, symbolic formulae, diagrams, tables, and simulations.

Open-ended learner input. The system allows the students to express themselves through natural language, drawing pictures, and other forms of open-ended communication.

One affordance that is comparatively rare in ITSs is *communication with other people*, such that the student communicates with one or more other people who are either peers or experts on the subject matter. However, some ITSs have an option that allows the student to have a chat interaction when they get stuck, such as www.tutor.com being used with a math tutor, with hundreds of human tutors available for chat interactions. Also, Hausmann et al. (2008) set up their ITS in physics with two students interacting with the ITS (without an agent) and showed benefits of the dyad over single student interactions. However, these two examples are exceptions rather than a frequent affordance of ITSs. Once again, however, there are many ITSs with conversational agents that serve as substitutes for communication with other people and thereby satisfy this affordance.

ITS mechanisms

The *Generalized Intelligent Framework for Tutoring* (GIFT; www.gifttutoring.org; Sottolare et al., 2018b) has articulated the frequent practices, standards (both pedagogical and technical), and computational mechanisms in ITS development. A framework is needed to scale up ITS for greater use in schools, industry, government agencies and the public. The GIFT initiative has a free publication series (in www.gifttutoring.org) with 20–30 experts contributing annually to particular thematic topics: Learner modeling, instructional strategies, authoring tools, domain modeling, assessment, team learning, self-improving systems, data visualization, and proficiency-based scenario design.

GIFT describes characteristics of the primary and frequent ITS components as well as more exotic components that are used infrequently. The *Learner Record* automatically stores the knowledge, skills, abilities (abbreviated as KSA’s) and other characteristics of each particular student that is collected before, during, and after the student interacts with the ITS. This is a rich history of interactions stored in log files, performance scores on tests, mastery of specific knowledge components, and often noncognitive characteristics (such as persistence, initiative, and particular emotions). The volume of data is far greater than what a human instructor could ever collect. A *Sensor* module senses and encodes multimodal input (if there is any) such as physiological states, geographical location, facial expressions, speech, and gestures. A *Pedagogical* module is the set of tutoring strategies and tactics that apply to particular types of knowledge, skills, and subject matter. A *Domain* module specifies the knowledge components, procedures, and other content associated with the subject matter being tutored. This content can range from texts and PowerPoint presentations to virtual reality and augmented reality environments.

One computational construct that is popular in the domain module of ITSs is a *knowledge component* (Koedinger et al., 2012). Intuitively, a knowledge component (KC) is a bite-size piece of information or skill that can be tracked and assessed in different contexts. For example, consider Newton’s second law of motion (net force = mass X acceleration). One could track how well a student’s performance reflects an understanding of this law in different contexts, such as answering a word problem, computing the speed of an object, or interacting with a physics simulation. The student might fail in one context but succeed in another. Newton’s second law is likely to involve a set of more specific KC’s, which researchers attempt to resolve through empirical research and debate. The important point is that such KC’s are fine grained and can be tracked over the student’s learning history. A *Q-matrix* is constructed for all of the tasks and problems in an ITS activity that specifies what KC’s are involved (there can be more than one for a problem) and what scores (0–1, continuous or discrete) to assign in the Learner Record store for each of the KC’s. New

problems and learning tasks can then be selected intelligently (through a *Recommender System*) that fills in missing KC's at the frontier (slightly beyond) what the student has mastered and gives opportunities to correct prior errors. It is important to acknowledge that the KC's are a major unit of learning in this approach. There are typically dozens to hundreds of KC's associated with a subject matter. This is a very different grain size than the traditional approach in education that assesses performance on a lesson or items on a test.

One limitation of the KC approach is that it assumes that there are correct answers that can be precisely specified. Some subject matters are more ill-defined, yet informative assessment and feedback can still be provided. For example, verbal answers to open-ended questions and essay grading have advanced considerably and are scored quite accurately, on par with human experts in many cases (Yan et al., 2020). Successful systems sometimes have no KC's. There is a rubric for assessing the quality of student contributions but no KC's per se.

A second computational construct that is popular in the Pedagogical module is the *production rule*. This consists of an IF <state> THEN <action> expression that specifies what the ITS should do under specific conditions (Anderson et al., 1995; Laird, 2012). The ITS watches over the landscape of current states in the Learner Record and Sensor modules. If a particular state exists or reaches some threshold of activation, a production rule is fired probabilistically. Contemporary rules need not be brittle, but rather are activated to some degree and probabilistically. They also are executed at any grain size, ranging from a very specific context (e.g., computing fractions with negative numbers) to an abstract generalization (e.g., suggestion to spending more time comprehending the lessons).

Performance of ITS in improving learning

Reviews and meta-analyses have shown that ITS technologies frequently improve learning compared to conditions in which students study text or experience classroom lectures and other activities, with some attempts to control for learning time. These meta-analyses normally report effect sizes (*d*) to convey differences between the ITS condition and a comparison condition in standard deviation units. The reported meta-analyses show positive effect sizes that vary from 0.05 (Dynarsky et al., 2007) to 1.08 (Dodds and Fletcher, 2004), but most hover between 0.40 and 0.80 (Kulik and Fletcher, 2015; Ma et al., 2014; VanLehn, 2011). A 0.60 performance is comparable to human tutoring which varies between 0.20 and 0.80 (Cohen et al., 1982; VanLehn, 2011), depending on the expertise of the tutor. Human tutors have not varied greatly from ITSs in terms of effect size in direct comparisons between ITSs and trained human tutors (Graesser, 2016; Olney et al., 2012; VanLehn, 2011).

Example ITS systems without conversational agents

ITSs have frequently been developed for mathematics and other well-formed subject matters in which there are objectively correct answers to questions. For example, *MATHia* (formerly *Cognitive Tutors*, Alevan et al., 2009; Anderson et al., 1995; Ritter et al., 2007), and *ALEKS* (Falmagne et al., 2013) cover basic mathematics, algebra, geometry, statistics, and more advanced quantitative skills. ITSs exist in other STEM areas, such as physics (Van Lehn et al., 2005) and information technology (Mitrovic et al., 2007). ITSs also cover topics that have a stronger verbal foundation as opposed to mathematics and precise analytical reasoning (Johnson and Lester, 2016). These are covered in the next section that focuses on ITSs with conversational agents.

Learning environments with conversational agents

Conversational agents may be rigidly scripted or may be highly interactive with conversations in natural language. Sometimes a scripted interaction is fine, as when students who have such low domain knowledge that they can only observe and not generate anything. Sometimes intelligent, adaptive, interactivity is crucial so that the student gets the right information at the right time.

There are many functions of conversational agents that should be considered in making decisions on the selection of a learning environment. A single agent conversing with a student can have different roles (mentor, tutor, peer, student to teach, adversary, help assistant, etc.), personalities, and persona (Baylor and Kim, 2005). An agent can be assertive and barge into conversations or wait to be called. The communication can range from simple chat without any persona image to 3D avatars in virtual environments (Johnson and Valente, 2009). Adding a second agent can dramatically increase the power of agents, as in the case of dialogues with a student interacting with a peer agent. Graesser et al. (2017) have identified various designs of agents in dialogues such as those below.

- (1) *Vicarious learning with student observer*. Two agents interact and model ideal social and verbal interactions, answers to questions, or reasoning. Craig et al. (2012) reported the benefits of students observing peer agents asking deep questions and receiving answers from tutor agents on physics and computer science domains.
- (2) *Vicarious learning with limited student participation*. The same as #1 except that the agents occasionally turn to the student and ask a prompt question, with a yes/no or single word answer. The question that invites an answer maintains human engagement and assesses student performance.
- (3) *Tutor agent interacting with student and peer agent*. There is a tutorial dialogue with the student, but the peer agent periodically contributes and receives feedback. When the student has low self-esteem, negative short feedback can be given to the peer agent

on bad answers (the agent takes the heat) whereas similar answers by the student receive neutral feedback. This triologue design has been applied in studies with AutoTutor for struggling adult learners who have limited ability to type verbal input (Graesser et al., 2019).

- (4) *Expert agent staging a competition between the student and a peer agent.* There is a competitive game (with score points) between the student and peer agent, with the competition guided by the expert agent. This would be appropriate for students who are motivated by competition. Jackson and McNamara (2013) used this triologue design in their instructional game iSTART-ME to improve reading comprehension on science topics.
- (5) *Student teaches/helps a student agent with facilitation from the tutor agent.* This is a “teachable agent” design (learning by teaching), with the tutor agent rescuing problematic interactions. More advanced students who can generate material might particularly benefit from this design. Biswas et al. (2016) used this design in *Betty’s Brain* on topics in biology.
- (6) *Student interacts with two peer agents that vary in proficiency.* The peer agents can vary in knowledge and skills. The Educational Testing Service is using this approach in conversation-based assessment (Jackson and Zapata-Rivera, 2015). The Program for International Student Assessment on collaborative problem solving (OECD, 2017) used this design to track whether the student corrects an incorrect contribution by a peer, correctly answers a peer question, and takes initiative in guiding the exchange.
- (7) *Student interacts with two agents expressing contradictions, arguments, or different views.* The discrepancies between agents stimulate cognitive disequilibrium, confusion, and potentially deeper learning. D’Mello et al. (2014) used this design to demonstrate that contradictions triggered cognitive disequilibrium in some students who experienced sufficient confusion that they resolved the contradiction and showed improvements in learning.

These examples of dialogues illustrate the potential of conversational agents in manipulating contexts and social situations in learning environments. There is an exciting future in research on conversational agents that go beyond two agents (i.e., including many agents), with each taking on different roles and functions.

Conversational patterns in human and computer tutors

Some agent-based ITSs have been influenced by systematic analyses of the discourse and pedagogical strategies of human tutors who vary from novices to experts (Chi et al., 2001; D’Mello et al., 2010; Graesser et al., 2009). Effective tutoring goes beyond lecturing and into the realm of guiding learners in a process of co-constructing solutions to problems, answering challenging questions, and designing projects. VanLehn (2006) has distinguished between the outer loop and inner loop in ITS structure. The outer loop is the set of major tasks for the tutor and student to work on whereas the *inner loop* consists of the steps that attempt to make progress within a major task. The inner loop of many human tutoring sessions and ITSs follows systematic patterns of interaction. One of these is the *5-step dialogue frame* (Graesser et al., 2009). Once a major task is selected, the 5-step tutoring frame is initiated with the following main steps: (1) the tutor or student present the main task, (2) the student generates an initial attempt to handle the task, (3) the tutor gives short feedback on the quality of the answer, (4) the tutor and student improve the quality of the answer through interaction, and (5) the tutor assesses whether the student understands the correct answer and follows up if necessary. Interestingly, classroom teaching normally (though not always!) involves the first three steps (Sinclair and Coulthart, 1975) but rarely steps 4 and 5.

An important question among ITS researchers is how to optimize step 4? AutoTutor (Graesser, 2016) and most human tutors (Graesser et al., 2009; D’Mello et al., 2010) apply an *expectation and misconception tailored dialogue*. The ITS typically has a list of *expectations* (anticipated good answers, steps in a procedure) and a list of anticipated *misconceptions* (errors or bugs) associated with each task. The ITS guides the student in generating the expectations through a number of dialogue moves: *pumps*, *hints*, and *prompts* for the student to fill in missing information. A pump is a move to get the student to provide more information, such as “What else?” or “Tell me more.” Hints and prompts are questions selected by the ITS to get the student to make decisions, generate content at a step, or articulate missing words, phrases, and propositions in the expectations. As the student generates contributions over many interactional turns and the tutor guides them or directly fills in missing content, the list of expectations is eventually covered and the task is completed. The ITS keeps track of how well the student does in covering expectations and not having misconceptions. The selection of the next task in the outer loop depends on the student’s profile in the prior history of performance on tasks in tutorial sessions.

Human tutors and ITSs give feedback to the student on their performance. There is both short feedback (positive, negative or neutral) and often qualitative explanations that justify correct versus incorrect answers. A typical ITS turn in a dialogue interaction has three components:

Tutor Turn → Short Feedback + Dialogue Advancer + Floor Shift

The short feedback addresses the quality of the student’s prior turn whereas the dialogue advancer gives either qualitative feedback or moves the tutoring agenda forward with hints, prompts, requests, or information to fill gaps. The third component, floor shift, provides a cue (e.g., question, gesture, facial expression) that it is the student’s turn in the exchange.

Most ITS attempt to accommodate a mixed-initiative dialogue by allowing students to ask questions, ask for help, and select tasks to work on. However, it is difficult or impossible for an ITS to anticipate all of the student questions, requests for help, or tasks to work on. This difficulty also applies to human tutoring to the extent that the tutor does not understand the student’s questions or

requests. When student initiatives are not understood or meaningfully taken up by the tutor, there is the risk of the student giving up trying to initiate questions and requests. This is one explanation of why the frequency of student questions and requests for help is low, even when students are encouraged to take the initiative (Graesser et al., 2009).

Example systems with conversational agents

Table 1 shows the highlights of 22 studies of ITS with conversational agents. All of these studies report empirical evidence on whether or not there are benefits from these agent-based ITSs over various comparison conditions. There are many different outcome measures in assessments of the systems' added value, such as subject matter learning gains, scores on psychometric tests of achievement, engagement with the system, self-reported impressions of the system, and other psychological attributes. It is beyond the scope of this chapter to summarize the results, many of which are subtle and involve aptitude-treatment-content interactions. Instead, we emphasize the broad scope of subject matters, learners, and pedagogical functions of these agent-based ITSs.

The main claim we wish to make from the systems in **Table 1** is that there is a broad scope of subject matters, learners, and pedagogical functions of the agents. The subject matters include mathematics, science, computer literacy, computer programming, electronics, human-computer interaction, and reading comprehension. There are also other systems not included in the table that address cultural practices. For example, the *Tactical Language and Culture Training System* has adults learn languages and cultural practices through virtual worlds with avatars (Johnson and Valente, 2009) and has been used by thousands of US soldiers deployed in Iraq. The learner age groups vary also, starting with children ages 3–6 in storybook reading, and encompassing K12 (elementary, middle, and high school), college, the military, and the workforce. The pedagogical functions run the gamut from constructing mental models of STEM topics to self-regulated learning and emotions. Given the diverse scope of these developed systems, we are convinced that agent-based ITSs could fill out the curriculum of schools, the government, the workforce, and extended education for citizens throughout the world. The combination of intelligent systems and human-like agents is at the very least a promising direction. At this point we will describe a few systems in more detail for readers who desire a more nuanced understanding of the nature of these agent-based ITSs.

AutoTutor

AutoTutor (Graesser et al., 2004; Graesser, 2016; Nye et al., 2014) was developed to simulate the discourse and pedagogical strategies of tutors and thereby help students learn by holding a conversation in natural language. AutoTutor goes beyond didactic lectures and into the realm of presenting problems to solve and difficult questions to answer that require a multi-turn conversation. AutoTutor implements the 5-step tutoring frame, the expectation and misconception-tailored dialogue mechanism, and the tutor turn composition that were described earlier. A list of *expectations* (anticipated good answers, steps in a procedure) and a list of anticipated *misconceptions* (bad answers, incorrect beliefs, errors, bugs) is associated with each task. As the students articulate their answers over multiple conversational turns, the contents of their contributions are compared with the expectations and misconceptions. The students' answers within each turn are typically short (one to two speech acts on average), vague, ungrammatical, and not semantically well-formed. AutoTutor compares the students' content to expectations and misconceptions through pattern matching processes with semantic evaluation mechanisms that incorporate research in computational linguistics. Examples of AutoTutor conversations can be found in on-line venues on the internet (sites.autotutor.org).

Listed below are tutor dialogue moves that frequently occur in the Expectation and Misconception Tailored dialogues in AutoTutor and in most human tutoring sessions.

Main question or problem. This is a challenging question or problem that the tutor is trying to help the student answer.

Short feedback. The feedback to a student's previous contribution is either *positive* ("yes," "correct," head nod), *negative* ("no," "almost," head shake, long pause, frown), or *neutral* ("uh huh," "okay").

Pumps. The tutor gives nondirective pumps ("Anything else?" "Tell me more.") to say more or to take some action.

Hints. The tutor gives hints to get the students to do the talking or take action, but directs the students along some conceptual path.

The hints vary from generic statements or questions ("What about X?", "Why?") to speech acts that nudge the student toward a particular answer.

Prompts. The tutor asks a leading question to get the student to articulate a particular word or phrase. Sometimes students say very little so these prompts are needed to get the student to say something specific.

Prompt completions. The tutor expresses the correct completion of a prompt.

Assertions. The tutor expresses a fact or state of affairs.

Summaries. The tutor gives a recap of the answer to the main question or solution to the problem.

Mini-lectures. The tutor expresses didactic content on a particular topic.

Corrections. The tutor corrects an error or misconception of the student.

Answers. The tutor answers a question asked by the student.

Table 1 Systems with conversational agents.

<i>Authors</i>	<i>System</i>	<i>Subject matters</i>	<i>Learners</i>	<i>Pedagogical function</i>
Adamson et al. (2014)	Bazaar: Academically Productive Talk (APT) agents	Biology, chemistry, engineering design	High school and undergraduate students	APT conversational agent supports on-line collaborative learning discussions

AutoTutor has shown learning gains of approximately 0.80 standard deviations compared with reading a textbook for an equivalent amount of time (Graesser, 2016). There are also different versions of AutoTutor that go beyond collaborative conversations on the subject content. One version of AutoTutor scaffolded students to take actions in a simulation world in addition to prompting verbal contributions of the students (Graesser et al., 2005). AutoTutor 3-D had the conversational tutor interact with students in a simulation on Newtonian physics problems. An example main question is: *When a car without headrests on the seats is struck from behind, the passengers often suffer neck injuries. Why do passengers suffer neck injuries?* The students are encouraged to manipulate values of variables (such as the mass, speed, and direction of vehicles) to see what happens when collisions occur in a 3-D world. The interactive simulation is a resource to help them answer the question verbally and to correct their answers when AutoTutor suggests they have misconceptions. Ideally, the students would spontaneously enact the Vary-One-Thing-at-a-Time (VOTAT) strategy in which values of one variable are varied while other variables are held constant (Greiff et al., 2013). VOTAT requires multiple runs of the simulation with systematic changes of the values and variables in order to construct a deep analysis of the system. Unfortunately, most students ran the simulation once and did not enact the VOTAT strategy. This is where an agent can step in and guide them to run multiple simulations and see the results of each simulation.

Another version of AutoTutor is sensitive to the learner's affect states, namely boredom, frustration, confusion, and flow (D'Mello and Graesser, 2012a). An empathetic AutoTutor helps learning for low knowledge students when they are frustrated or experiencing other forms of negative affect. ITS researchers have been sensitive to learner's affective states in addition to their states of knowledge and cold cognition (Arroyo et al., 2014; Baker et al., 2010; DeFalco et al., 2018).

Inq-ITS

Inq-ITS (Inquiry Intelligent Tutoring System; www.inqits.com) is a simulation-based intelligent tutoring and assessment system that supports teaching, learning, and assessment of scientific inquiry practices in the domain of life, earth, and physical science (Gobert et al., 2013). These scientific practices are aligned with the Next Generation Science Standards (NGSS Lead States, 2013) and a national framework for K-12 science education (NRC, 2012) with the goal of helping middle school students to develop key inquiry skills as scientists do. Students practice five primary scientific inquiry practices within Inq-ITS: asking a question/forming a hypothesis, collecting data to test it, interpreting data, warranting the claim with data, and communicating findings via written claim, evidence, and reasoning statements. The first four practices involve practicing science, whereas the last one involves writing about science. A pedagogical agent, Rex (a cartoon dinosaur), offers students real-time, personalized scaffolding that adapts to the quality of students' inquiry practices as they engage in virtual labs (Gobert et al., 2018; Li et al., 2018). The teacher dashboard Inq-Blotter, a mobile alert system, informs teachers of students' performance on inquiry practices and provides them instant alerts on which students need one-on-one support most and when whole-class instruction is necessary.

The implementation of personalized assistance within Inq-ITS and teacher's alerts within Inq-Blotter depends on the automated evaluation of students' science inquiry practices by leveraging techniques from educational data mining, knowledge engineering, and natural language processing. The computational procedures and algorithms are employed to automatically score students' actions and interactions within each practice with robust features that were developed through manually scoring log files and automated training assessment models. For example, these models can identify an independent variable (IV), identify a dependent variable (DV), and interpret/warrant the IV/DV and hypothesis/claim relationship. The automated scoring has been shown to robustly match human scores with high precision, ranging from 84% to 99% accuracy among diverse groups of students (Gobert et al., 2018).

Inq-ITS has also applied pattern match NLP techniques and if-then algorithms to automatically score the communicated findings involving written claim, evidence, and reasoning statements in the open-ended response format (Li et al., 2017a,b). Specifically, regular expressions are used to determine the presence or absence of key concepts or complex phrases within written responses. Regular expressions identify alternative forms of words and expressions including misspellings (e.g., /indic/capturing different forms of indicate, i.e., *indicate*, *indicates*, *indicated*, *indicating*, *indication*, *indicote*, and *inducution*) and syntactic precision of wording (e.g., *I increased the temperature so it increased the number of animals with green short furs* vs. *I increased the number of animals with green short fur so it increased the temperature*). The automated scoring is highly correlated with human scores with r equal to 0.94, 0.97, and 0.84 for written claim, evidence, and reasoning, respectively (Li et al., 2017a,b).

The automated assessment of students' practices allows for real-time adaptive scaffolds (Gobert et al., 2018; Li et al., 2018) in addition to building the teacher dashboard. The pedagogical agent (Rex) provides students different types of scaffolds based on their performance, consisting of orienting scaffolds (i.e., directing attention to a particular step), conceptual scaffolds (i.e., explaining an inquiry practice required for the step), procedural scaffolds (i.e., informing students of the procedure for the step), and instrumental scaffolds (i.e., guiding students how to move forward on a step). The adaptive scaffolds effectively improve students' inquiry practice competencies, with both near and far transfer of these practices over time and across inquiry topics with effect sizes ranging from 0.18 to 1.80 (Gobert et al., 2018; Li et al., 2018).

Conversational agents in an informal learning setting

The increasing emergence of digital devices, particularly mobile technology, facilitates an upsurge of informal learning that is not constrained to learning at schools. The museum is a primary location where students become motivated and engaged in science and technology. If a museum guide can enhance the interactive exchange with visitors rather than merely present information, the visitors will gain a deeper understanding of museum content (Swartout et al., 2013). Due to the short supply of human museum guides, the virtual human guide is a potential museum guide to improve the quality of interactions between visitors and the guide. Swartout and colleagues have investigated the efficacy of virtual museum guides in interacting with visitors, engaging visitors, and increasing their understanding of the museum content (Swartout et al., 2013) in the *InterFaces* project, a collaboration between the University of Southern California and the Museum of Science in Boston. *InterFaces* is an exhibit where virtual human guides, called Ada and Grace, are housed and designed to promote interest and engagement in STEM topics, targeting children between ages 7 and 14. Ada and Grace are twins designed to increase engagement using the following four elements: (1) an appealing appearance of a young adult female with an indeterminate racial background that the museum visitors selected with traits of being friendly, smart, and patient, (2) near photoreal appearance of the twins that are created using light stage technology and digital artists to appear and animate realistically, (3) generation of responses to questions posed by museum visitors to better maintain the pace of the conversation and visitor interest, and (4) natural language understanding through the acoustic speech and language models that are customized to individual staff members' voices to increase the speech recognition accuracy. Evaluation of natural language performance showed that 70% of the public's spoken utterances to the characters matched expected utterances by the computer system. Among the known utterances, over 80% were answered correctly, with failures typically attributed to poor speech recognition. Aside from the accuracy of answers to questions, the Ada and Grace twins were impressive in both entertaining and motivating children to learn about science.

Challenges for the future

In this chapter we have articulated the need for ITS, particularly those with conversational agents. We have identified many successful ITS learning environments that are backed by empirical support—they have had a positive impact on learning, engagement, and/or impressions on the learner. However, the picture is not uniformly rosy. There are limitations and challenges to face in the future for those who want to build, test, and adopt these digital learning environments. This section identifies the major obstacles that have prevented ITS from reaching many millions of learners throughout the globe. Perhaps these obstacles will be solved in the next generation.

One obstacle is that it has historically taken a large amount of time and money to build ITSs because of the complexity of the mechanisms and the limited number of competent experts to build them. The GIFT community (Sottilare et al., 2018a,b; gifttutoring.org) has been attempting to reduce the cost and time through modularity, standards, and better authoring tools. However, the cost is still measured in millions of dollars and the time is measured in years. Once a good system is built, it can be disseminated to millions of people, which dramatically reduces the cost per learner. However, this requires capital investments and marketing, which has not yet occurred for ITSs at the volume of other digital learning technologies, such as Massively Open Online Learning (MOOC) systems (Siemens et al., 2015).

A second obstacle is that it is difficult to develop authoring tools that can be productively used by individuals without expertise in computer science. The ideal person or R&D team would have expertise in the subject matter knowledge, intelligent tutoring systems, conversational agents, discourse processing, and pedagogy—a rare combination of skills to assemble.

A third obstacle is uncertainty as to how much human intervention and support is needed to implement ITSs (either with or without conversational agents) in real world contexts. Instructors are increasingly turning to *blended learning* environments in which the instructor attempts to weave in these sophisticated technologies like ITSs (Lesgold, 2019; Siemens et al., 2015). Unfortunately, we are at a point in history when the existing professional development (i.e., training of teachers) is not keeping pace with advances in technology and consequently not meeting the needs to have instructors integrate computer technologies in the curriculum and practice. This challenge of course exists for all digital learning technologies. However, ITSs are comparatively complex and some computational components are difficult to explain to instructors who want to know how they work.

A fourth obstacle is relevant to those ITSs with conversational agents. These systems have limited mixed-initiative dialogue and affordances for self-regulated learning. Each system covers a rather specific topic so they cannot provide support for all questions, topics, problems, or tasks that students initiate unless the ITS has already developed them ahead of time. Even for a specific topic, students ask a broad diversity of questions, with many unanticipated by the ITS. Consequently, the learning leans toward being instruction-centered or tutor-centered more than student-centered. Perhaps these limitations will be reduced in the future when there are thousands of ITSs developed on a wide range of topics and when data repositories are so large that the likelihood of a student asking a unique question about a topic is vanishingly small. That will hopefully evolve in the emerging era of Big Data.

Introduction

Mindfulness is the intentional moment-to-moment focus on the present, while treating inevitable intrusive thoughts and feelings with an attitude of curiosity and nonjudgement (Bishop et al., 2004). Mindfulness-based interventions (MBIs) that train this ability are an increasingly popular way of attempting to enhance the cognitive, emotional and behavioral outcomes of adults and young people, with studies showing improvements in a host of areas including anxiety and depression (Hofmann et al., 2010), cognitive skills (Chiesa et al., 2011) and disruptive behavior (Klingbeil et al., 2017). However, studies seldom target mindfulness' utility in improving learning. Learning, the process of gaining new skills, knowledge and understanding, is crucial for improving performance and sustaining achievements. The following review and meta-analysis elucidates the relationship between mindfulness and learning based on existing literature. Although learning is a continuous process that occurs throughout the lifespan, the following focuses on young people in education.

How could mindfulness training improve learning?

Mindfulness has been practiced for around 2500 years, though formal MBIs have been around for less than 50. Three of the most popular and enduring MBIs that were originally designed for adults, but have been adapted for use with children and adolescents are: Mindfulness-Based Stress Reduction (MBSR; Kabat-Zinn, 1982, 2003), Acceptance and Commitment Therapy (ACT; Hayes et al., 2009) and Mindfulness-Based Cognitive Therapy (MBCT; Segal et al., 2002). MBSR was the earliest example of a formalized MBI and was developed to help adults learn to manage illness, pain and stress. Later, ACT sought to help individuals overcome negative thoughts and feelings through acceptance, and MBCT focused on helping to prevent the recurrence of depression. So, if MBIs were typically designed to help us manage stress or prevent reoccurrence of depression, why could they also improve our ability to learn?

First, there is evidence to suggest that MBIs may improve executive functions (Frank et al., 2021; Grabovec et al., 2011; Lam and Seiden, 2020; Shapiro et al., 2006). Executive functions are a set of mental skills required for managing our thoughts and behaviors that are also important for learning and academic achievement (Duncan et al., 2007; St. Clair-Thompson and Gathercole, 2006). These include working memory, planning, organization, task initiation, flexible thinking and most relevant to this review—emotional and attentional control, inhibition, and self-regulation. Using MBI's to improve learning via enhancement of executive functions makes theoretical sense. The ability to focus attention is a cornerstone of both mindfulness practice and successful learning (Fisher, 2019; Steinmayr et al., 2010; Valentine and Sweet, 1999). Indeed, sustaining attention, in particular, appears to play an essential supporting role in enhancing other cognitive functions such as memory (Fortenbaugh et al., 2017) and is related to

academic success (Polderman et al., 2010; Posner and Rothbart, 2005). Similarly, MBIs have also been shown to improve self-regulation skills, such as self-monitoring (i.e., understanding and adjusting our behaviors) and inhibition (i.e., how we control our impulsive responses), which are again important for learning (Holzel et al., 2011; Panadero et al., 2012; Van der Sluis et al., 2004; Zimmerman and Shunk, 2011). If mindfulness practice requires attending to one's own present moment thoughts and feelings and treating intrusive thoughts nonjudgmentally without trying to engage with or change those thoughts, then, in theory, this requires sustained attention, self-monitoring, and inhibition.

Second and more indirect, learning during the school years coincides with a particularly vulnerable period for the onset of psychopathology; indeed, adolescents, in particular, are susceptible to mental illness with 50% of mental health problems having their onset before the age of 18 and 75% before the age of 24 (Kessler et al., 2005). Emotional turmoil that manifests as anxiety, depression or loneliness can make the school years a challenging time for young people and can negatively affect their learning experience. Because MBIs are useful in helping reduce depression and anxiety in young people (e.g., Dunning et al., 2019) and in preventing relapse of depression (e.g., Kuyken et al., 2015), it seems sensible to suggest that if a student is less concerned with mental health issues, they would more likely find it easier to learn.

What is the evidence that mindfulness training improves learning?

Given the importance of learning and the increased use of MBIs to improve outcomes in young people, the evidence for mindfulness improving learning is surprisingly sparse. A meta-analysis by Klingbeil and colleagues included five studies of varied design (i.e., randomized controlled trials (RCTs), quasi-randomized trials) that included a wide range of measures of academic achievement (e.g., school grades) and school functioning (e.g., classroom participation, student behavior). Although the meta-analysis showed MBIs improved academic achievement and school functioning (hedges' $g = 0.32$ (pre-post trials), $g = 0.39$ (controlled trials)) the authors acknowledged that the results contained publication bias and large standard errors, which were likely the result of the broadness of included outcomes and varied trial designs (Klingbeil et al., 2017).

Maynard et al. (2017) in a review and meta-analysis of school-based MBIs found five studies that included measures of academic outcomes (school grades and academic credits). They found small but non-significant effects on learning (hedges' $g = 0.27$, $p = 0.08$) and further concluded that the studies showed a high risk of bias. Indeed, the studies included in their review were a mixture of RCTs, quasi-experimental trials, single-group pre-post designs and single-subject designs.

Since the publication of these two reviews, there has been a considerable number of new studies examining the effects of MBIs on young people, including a twofold increase in the number of RCTs (Dunning et al., 2022b). This allows a more comprehensive analysis of the effects of MBIs on learning.

In the following, I present a meta-analysis of the benefits of MBIs for improving the learning outcomes of young people. A key feature of this meta-analysis is that the included studies are all RCTs, the gold standard in research methodology. Including only RCTs protects against both test-retest effects and the effects of maturational changes. Furthermore, as participants are randomized to group, it increases the likelihood that there are no systematic differences between groups that might be confounded with the treatment condition. The following also allows the separate analyses of MBIs compared against passive control groups (e.g., no contact, teaching as usual, wait-list) or active control groups (e.g., another intervention). Meta-regressions are used to investigate several variables of interest. First, as bias has been shown in other meta-analyses, we can ascertain if the quality of individual studies (risk of bias) affect results when analyzing only tightly controlled RCTs. Second, we can explore if the dosage of training is related to learning improvements—specifically does more mindfulness practice mean better results. Third, we can assess if MBIs are more beneficial for improving the learning of younger or older age groups. Additionally, we examine if publication bias is present and, by means of studies that included follow-up assessments, whether effects of MBIs on learning are sustained or relatively short-lived.

Method

Search strategy and inclusion criteria

Literature searches for published and unpublished articles from January 1990 to January 2022 were conducted, using the electronic databases Pubmed, PsycINFO, EMBASE and Google Scholar. The search terms and Boolean operators used were ((“mindful*”) AND (“child*” OR “school” OR “adolescen*” OR “youth”)). Because “learning” is a broad concept, this was not included in the search terms as it was feared studies would be missed if the search terms were too prescriptive. The reference lists of reviews and meta-analyses were also searched for suitable studies. After searches were collated and duplicates removed, the titles/abstracts of the remaining articles were reviewed. If the title/abstract suggested that the study included a learning outcome (e.g., reading, maths, grades, academic achievement) then the full-text article was downloaded and compared against the following inclusion criteria:

- (i) The effects of mindfulness were evaluated against a control condition and the participants were randomized to condition;
- (ii) The outcome measures used were related to learning outcomes and the paper provided quantitative data from which effect sizes could be calculated (means and standard deviations).

Ten studies met these criteria and were synthesized in the analyses.

Data extraction and synthesis

For each study the following variables were recorded: age of sample, total number of participants (i.e., number in MBI group plus number in control group), type of control condition(s), total hours of mindfulness training (i.e., sessions x duration in minutes, excluding home practice), type of mindfulness practice (e.g., MBSR, MCBT), learning outcome reported and follow-up period (if applicable). All of this information can be seen in [Table 1](#).

Between-group effect sizes (Cohen's *d*; [Cohen, 2013](#)) were calculated based on the mean pre-post change in the MBI group minus the mean pre-post change in the control group, divided by the pooled pre-test standard deviation ([Morris, 2008](#)). The pooled pre-test standard deviation was used so the intervention could not have influenced the standard deviation, based on the recommendation by [Carlson and Schmidt \(1999\)](#). A positive effect size indicates that the MBI group benefitted more than the comparison group. Effect sizes were interpreted on the following basis: $d = 0.20$, a small effect; $d = 0.50$, a moderate effect; and $d = 0.80$, a large effect ([Cohen, 2013](#)). If a study used multiple measures to assess learning, then a mean of the effect sizes was calculated on pre-to post-intervention effects. A full list of the learning outcomes used, with their effect sizes can be seen in [Appendix 1](#).

Analysis

All analyses were conducted using the Comprehensive Meta-Analysis program version 3.3.70 ([Borenstein et al., 2021](#)). Confidence intervals were calculated for effect sizes.

Due to variation in studies in features such as age of sample, learning outcome used, and type of MBI used, a random effects model was chosen for all analyses. All 10 studies were included in initial analyses. Additionally, separate analyses were conducted on the six studies that used an active control condition, the five studies that used a passive control condition (note: [Zelazo et al., \(2018\)](#) used both active and passive control groups), and the six studies that included a follow-up assessment.

Individual, random-effects meta-regressions assessed the impact of three moderator variables: (1) age of sample, to establish if younger or older participants benefitted most from MBIs; (2) total hours of MBI, to explore if the dose of mindfulness training affected learning outcomes; and (3) risk of bias, to ascertain if study quality influenced learning outcome. For the studies that included a follow-up assessment, an additional moderator variable was used: 4) time since follow-up (i.e., the time between post-assessment and follow up) to establish if any effects of MBIs strengthen or fade over time.

Table 1 Details of all studies included in the meta-analysis.

Authors	<i>n</i> Sample	<i>n</i> Mindfulness Controls	Age (mean)	Mindfulness training	Control group	Learning outcome	Duration of training (hrs)	Follow up period (mths)	Risk of bias

Note: for risk of bias: (1) random sequencing; (2) allocation concealment; (3) blinding of outcome assessment; (4) incomplete outcome; (5) selective reporting.

Heterogeneity, the amount of diversity in the characteristics of the outcome measures, was quantified using the Q statistic and I^2 estimates. For I^2 estimates, a value of 0% equates to no heterogeneity, 25% to low heterogeneity, 50% to moderate heterogeneity and 75% to high heterogeneity (Higgins et al., 2003).

Risk of bias

The Cochrane Collaboration's Risk of Bias Tool (Higgins et al., 2008) was used to assess study quality. This involves making evidence-based judgments about specific features of each study to establish if biases exist that could lead to an overestimation or underestimation of the true intervention effects. Risk of bias was graded in terms of the following categories: (1) random sequencing—if the method used to randomly allocate participants to group was appropriate; (2) allocation concealment—if allocation to condition was concealed from participants during enrollment; (3) blinding of outcome assessment—if assessors were unaware of study condition; (4) incomplete outcome data—if missing outcome data were appropriately reported and/or given appropriate statistical treatment; (5) selective reporting—the degree to which studies reported all pre-specified outcomes.

Each of the five risk of bias categories for each study was awarded one of three ratings: a “minus” indicated a low risk of bias; a “plus” indicated a high risk of bias, and a “question mark” was used if the risk of bias was unclear. To enable the use of risk of bias as a moderator of the effects of MBIs on learning outcomes, a discrete variable was calculated. For each of the five categories for each study, each “plus” given a value of 1, each “question mark” a value of 0 and each “minus” a value of -1 . Therefore, individual studies could have a risk of bias score of between -5 and 5 , with higher scores indicating a higher risk of bias.

To investigate publication bias, the extent to which the studies included were representative of the population of studies, a series of Begg's funnel plots and Egger's regressions were conducted for each analysis. Missing data were imputed using the Duval and Tweedie trim and fill method.

Results

Table 2 shows the results of the meta-analysis. Across all studies, the learning outcomes of participants receiving an MBI improved significantly more than those receiving the control conditions (across active and passive conditions), with a small effect size ($d = 0.26$). For sub-analyses of the six studies that compared MBIs against active control conditions and the five studies that compared MBIs against passive control conditions, results were non-significant—though MBIs versus active control groups approached significance ($d = 0.16$, $p = 0.06$).

Analysis of the six studies that included follow-up assessments showed that MBIs were more effective than control conditions (the analysis contained a mixture of active and passive control groups) in improving learning outcomes, with a small effect size ($d = 0.24$).

Forest plots of all analyses can be found in Appendix 2.

Heterogeneity

Heterogeneity was present for analysis of all studies and the studies that compared MBIs against passive control groups, with significant Q values of 26.60 and 23.75 respectively. I^2 estimates suggested heterogeneity for significant outcomes was moderate to high in size. Heterogeneity statistics can be seen in Table 2.

Risk of bias

There was a low risk of bias in 40% of the studies for random sequencing, 0% for allocation concealment, 10% for blinding, 40% for incomplete outcome data, and 60% for selective reporting. A high risk of bias existed in 20% of the studies for random sequencing, 50% for allocation concealment, 60% for blinding, 30% for incomplete outcome data and 20% for selective reporting. In all other cases the risk of bias was unclear. For the risk of bias of individual studies, see Table 1.

Table 2 Analysis of effects of MBIs on learning, when compared with active/passive control groups, and at follow-up assessment.

	k	Number of effect sizes	Total n	Intervention effects					Heterogeneity			Publication bias (Eggers)	
				Mean effect size (d)	SE	95% CI	Z	p	Q value	p	I^2 (%)	t	P
All studies	10	33	911	0.26	0.13	[0.01–0.50]	2.05	<0.05	26.60	<0.01	66	1.12	0.29
Active controls	6	21	565	0.16	0.09	[−0.01 to 0.33]	1.89	0.06	3.04	0.69	0	0.76	0.49
Passive controls	5	12	418	0.32	0.25	[−0.18 to 0.81]	1.26	0.21	23.75	<0.01	83	1.24	0.30
Follow up	6	22	608	0.24	0.12	[0.11–0.48]	2.06	<0.05	8.41	0.14	41	0.18	0.86

There was no evidence of publication bias in any analysis, suggesting that the studies included here are representative of the wider literature (see [Table 2](#)). Funnel plots for all analyses can be found in [Appendix 3](#).

Moderator analysis

Neither age nor hours of mindfulness moderated outcome in analysis of all 10 studies, MBIs versus active controls or MBIs versus passive controls (all $ps > 0.5$). However, for MBIs that included a follow-up assessment, age significantly moderated learning outcomes with younger participants experiencing larger learning gains following MBIs (compared to controls) than older participants. Likewise, hours of mindfulness moderated learning outcomes at follow-up, with a bigger dose of mindfulness equating to larger effects. Risk of bias moderated improvements in learning following MBI for studies that compared MBIs against passive control groups and for studies that included a follow-up. The pattern here was different with a higher risk of bias equating to a lower effect size for MBIs compared to passive controls and lower risk of bias equating to lower effect sizes for MBIs at follow up. Length of follow-up (i.e., time elapsed since post-assessment) did not moderate performance at follow up.

Discussion

This is the first meta-analysis composed entirely of RCTs that examines if MBIs improve learning. It included separate analyses of MBIs versus active and passive control groups, and analysis of studies with follow-up assessments. A previous meta-analysis showed that MBIs significantly improved learning outcomes ([Klingbeil et al., 2017](#)), whereas another showed non-significant findings ([Maynard et al., 2017](#)). However, both previous studies were small, with only five studies included in each, and demonstrated high bias, possibly due to the varied research designs included in the study samples. Although the meta-analysis reported here is also relatively small, it includes double the number of studies of previous meta-analyses. Additionally, as its focus was exclusively on RCTs that by design are methodologically more robust than non-RCTs, there should be a lesser chance of bias.

Results revealed that MBIs did not significantly improve learning outcomes when compared to either passive ($k = 6$) or active ($k = 5$) control groups. However, when all studies were considered (i.e., both active and passive control groups included in the same analysis), MBIs showed small beneficial effects on learning ($d = 0.26$). For studies that included a follow-up assessment ($k = 6$), there was also a significant small positive effect of MBIs compared to controls ($d = 0.24$). Taken together, this evidence, though not compelling, is promising and warrants further investigation.

Moderator analysis revealed that age and hours of mindfulness did not moderate performance in analysis of MBIs versus active controls, or MBIs versus passive controls, or all studies. However, risk of bias did moderate performance in analysis of MBIs versus passive controls, with a higher risk of bias associated with lower effect sizes. For moderator analysis of follow-up studies, a larger dose of mindfulness (i.e., more hours of practice) suggested better learning outcomes, age moderated results at follow-up with younger participants benefitting more from MBIs than older ones and risk of bias moderated learning outcomes with a higher risk of bias associated with larger effect sizes, suggesting that studies of lower methodological quality may have inflated the overall effect size.

There was no evidence of publication bias, signifying that the trials included here were not systematically different from unpublished studies. However, risk of bias analysis showed that bias was present in some form in all 10 studies included in the review, particularly with regard to allocation concealment (if allocation to condition was hidden from participants during enrollment) and blinding (if assessors were unaware of study condition).

Even though RCTs are the gold standard research design, there were still relatively few mindfulness studies suitable for inclusion in this review. Indeed, the positive effects for studies at follow-up is based on analysis of only six studies and includes three taken from a single unpublished doctoral dissertation. Furthermore, the longest follow-up period of included studies was three months after cessation of training. The prospects of the effects of MBIs enduring for longer should therefore be explored. Although the focus here was on young people in education, there was a wide age range of participants in the included studies that stretched from kindergarten (4 years of age) up to 1st-year university students (18+ years). This makes understanding exactly how mindfulness improves learning a challenge. If we accept that improvements in executive functions lead to downstream improvements in learning outcomes, then we also need to consider that as different executive functions emerge at different times (and rates) across childhood and adolescence (e.g., inhibitory control usually emerges in early childhood and predates skills such as cognitive flexibility), then MBIs might also work in very different ways at different stages of childhood and adolescence. Another issue worth considering is that most of the studies included in this review tested different MBI protocols rather than run replication studies with established MBIs. Indeed, of the studies included in this review, there was only one MBI that was used more than once (i.e., dot.be). This problem extends to the wider field (see [Dunning et al., 2019](#) for a discussion) and, as mindfulness is a broad construct and interventions using mindfulness programs differ in terms of content, implementation, fidelity and duration (including home mindfulness practice), it makes drawing meaningful conclusions about how MBIs work difficult. There was also heterogeneity present in several analyses that suggests a lack of similarity between studies, in this case perhaps with regards to the different types of MBIs used or the wide age range of included participants.
